The leaders of the trade feel that something ought to be done to elevate their community in professional knowledge, and they established the Pharmaceutical Society to accomplish this great work—with what measure of success recent events show. The public must not have mere machines to make up prescriptions—men who,

without a single caution, will send from their emporiums poisons which will kill

"As swift as hasty powder fired

Doth hurry from the fatal cannon's womb,"

and then shelter themselves under the leaf of paper marked with the hieroglyphics of medicine.

The Cronin affair teaches us further to make up, where we can, our own prescriptions. Some very delicate physicians in small practice would, doubtless, think it a pretty thing to be compelled to use their abundant leisure in saving Corfields' scientific blunders, and Miss Collyers' tragic deaths. Fashion, we admit, is a strange thing; but for the life of us we cannot see why it is dignified to prescribe and derogatory to dispense; and this, too, when there is more leisure for the one than knowledge for the other.

Mr. Cronin has been severely censured, and not without reason; yet it is enough for him to bear his own stripes, without receiving those which are due to Messrs. Bell and Corfield. Had he acted his own apothecary, as at first, he might not now have been chewing the cud of self-mortification. But how could Mr. Bell have sent from his shop a bitter-almond water of such strength as to prove fatal to life in a small dose, without a caution: knowing, as he states in his evidence, that there were *two-and-twenty* different descriptions? He had no means of knowing he says, for what purpose it was to be used, and, therefore, in his ignorance, he commits just the same error as Dr. Cronin, by not specifying the strength of the water sent. Mr. Corfield is perfectly ignorant about the varieties—so it is *amygd. amar.* he cares not—nor does he take any trouble to enlighten his darkness till the astounding intelligence is brought that one draught consigned the young and unsuspecting girl to the embrace of death!

We remember, some years ago, that a gay druggist's apprentice, wishing to spare himself trouble, kept for this purpose, by him, a good stock of *peas*, ready coated with powder—not for soup, but pills; and for some time he comforted the bowels of his master's customers by administering them instead of nauseous physic. An old gentleman, with bowels which wanted rather to be disturbed than comforted, complained to his physician—the dose was increased; no movement, however, was produced, till at length the patient, wearied by flatulence and peas, brought the supposed pills to the druggist, who, in his attempt to break one, discovered the fraud, and relieved the gentleman. This freak of the apprentice was comparatively an innocent one, so far as the peas were concerned, but it must have been a source of disappointment to the prescriber, and might have lost him many guineas if the trick had not been discovered in time. The profession have not yet acquired the lesson that their safety and success are often connected with the dispensing of their own medicines.

We are taught, too, the necessity of medical reform. The public are taken with high-sounding titles; the members of the profession know it, and numbers hang out the imposing letters as a bait, which is swallowed by the unwary without thinking of a hook. 'Time was when there existed post-office dubs, now there are *Giesen* doctors; and, under the present order of things, there will be men who will deal in parchment, that they may dabble the more successfully in physic.

For the sake of all that is good, may we speedily have such a change as shall put down quackery of every description, whether in diplomas, advertisements, or cunningly worded inquiries ad-

dressed to professional brethren. With the renovation of the medical body, the druggists will receive such benefit that they shall not be mere fools to physic or poison her Majesties subjects.

TREATMENT OF PAUPER LUNATICS.

IN another part of our columns will be found an account of a prosecution of two individuals by the Commissioners of Lunacy, for brutal conduct to an insane pauper named William Rank. The prisoners were engaged as assistants in one of the wards of the asylum in which the unfortunate patient was lodged, and under their brutality died. The *post-mortem* examination showed fractures of three or four ribs, with perforation of the pleura. Such is doubtless the melancholy end of many entitled to our sympathy, not only because poor, but because deprived of that which constitutes and dignifies the man—his mental faculties. Of all the misfortunes that can happen to an individual, this surely is one of the most appalling. If benevolent feelings are called into exercise on the contemplation of ordinary suffering, how much more ought they to be exercised when poverty and madness combine to afflict an individual? Much has been done to alleviate the sufferings of those who are the inmates of eleemosynary lunatic institutions; and it is right that Government should keep a strict watch over the conduct of those who act as officers in these places. The time is gone by when it was considered necessary to use gags and chains and brutal lashings to tame into submission the unfortunate subject of mental disease; and one powerful means to prevent a recurrence of these enormities is for the public to manifest an interest in all that pertains to the comfort and ultimate restoration of this class of unfortunates. It is to the credit of the medical profession that its members have appeared in the front rank of benefactors to the insane. Attention has been strenuously directed to the best means of soothing them in their affliction, and of ultimately restoring them to the enjoyment of wanted health; and it is to the profession that the public are indebted for the abolition of those barbarous and disgusting practices which increased rather than diminished the malady so ill treated. It would be an act of injustice to us, as well as to the unfortunate patients themselves, if any maltreatment, by servants or others, should go unnoticed or unpunished. The public should have the whole benefit of our improvements.

DR. WRIGHT'S CLINICAL LECTURES.

Our readers are generally aware, in the best way we hope—by the possession of the pamphlet—that Dr. Wright has published the masterly Lecture introductory to the course which now weekly ornaments our columns in a separate form. Our contemporary, the organ of the Provincial Medical and Surgical Association, bears, in its last number, the following handsome testimony to the writings of our experienced and able contributor:—

"We are induced to notice this lecture by the Clinical Professor of Queen's College, Birmingham, chiefly because it emanates from one of our provincial schools. The observations of its author are highly judicious, and embrace a brief summary of what is expected and required of those entering into the medical profession, to render themselves competent to the serious duties on which they are about to embark. 'There is no nobler profession than ours,' ob-

serves Dr. Wright, in his concluding remarks, "and there is none more responsible. There is something awful in having to take charge of human life; it tells us that we have both a moral and a medical duty to perform to our patients. Never look to the worldly condition of individuals, to know how much professional attention you are to pay them, and what claims they are to have upon your sympathy with their sufferings and anxiety for their welfare." We regret we have not space for the entire passage; it is replete with the highest principles of medical ethics, and happy will it be for the students of the school if such principles sink deep into their minds, and become those on which they shall hereafter be guided in the exercise of their professional calling."

SHERIDAN KNOWLES.

OUR friend (it is our pride to call him so) whose name, illustrious, forms the heading of this article has favoured us with a brief acknowledgment, intended to be public, of his obligations for restored health to the good offices of Dr. Charles Mackintosh, a homœopathic practitioner, of Torquay.

Cowper says—

"What obvious truths the wisest heads may miss!"

and the great dramatist is here no bad illustration of the aphorism! We, who know the robust and vigorous constitution, the happy temper and temperament, the inflexible temperance, the careful regimen, and wise habits of our friend, see as a "simple and obvious truth," that such a man—and at Torquay too—required no medicine to recover from any little debility or exhaustion arising from *facilities* much and sedentarily exercised. Mr. Knowles wanted no remedy but rest—a fact which, as a physician *himself* and the intimate of our immortal Jenner, he must have suspected; and, because that rest had its tedium lightened by homœopathic manipulations, the bard gives to Dr. Mackintosh the praises really due to his own care of a constitution magnificently worth it! There is a peculiarity in Knowles's once "missing a truth" as in his general rule of hitting it: 'tis done with a thorough good-heartedness. In his generosity to friends he can even fall into a blunder, and to his own disservice: a very practical antithesis to the conduct of that Government which, in point of gratitude, good feeling, and good taste, should never hear the name of Knowles without a blush!

THE HOUNSLOW INQUEST.

WE can state on authority to which we attach perfect credence, that some of the parties who have been injured by the way in which the Hounslow Inquest was conducted, and by the manner in which their characters and opinions were subsequently criticised, at certain public meetings, by the coroner who presided on that occasion, are about to move the Court of Queen's Bench for a criminal information against that honourable functionary.

FALSE MEDICAL CERTIFICATES.

WE understand that the case of a person in the western counties who secured a fellowship in the College of Surgeons by a course of studies carried on in a baker's shop, and which was brought under professional notice some time ago in the *Medical Times*, is now receiving the consideration of the authorities in the College of Surgeons; and that a prosecution for false certificates is likely to be instituted against the offending party.

WIDOWS AND POISONS.

(From the *Pharmaceutical Times*.)

Widows may now be divided into two great classes—the voluntary and the involuntary—those who could have prevented their widowhood, and those who could not!

Should the reader be startled at the boldness of our proposition, or think this classification of widows uncalled for—at least in our pages—let us inform him now, at once, in our very prologomenon, so to speak, that this classification is absolutely necessary to the justification of our coming remarks.

The pale-faced widow, who, still in the heyday of life and health, mourns with unfeigned grief the loss of the partner of her youth—whom she loved, honoured, and obeyed in health, nursed in sickness, wept over in death, and followed with heartfelt sorrow to the grave—she honours the black crape! Heaven forbid that any levity of ours should alight upon her! but not whole torrents of hypocritical tears, whole wardrobes of black crape, or the shroud-like, plaited, impressive ugliness, the widow's cap,—or any other outward sign of flesh mortified and spirit subdued, can lessen our horror and indignation of that hybrid abomination,—half goat, half tigress, under the form of widow, who, to facilitate the enjoyment of her own little amours, cuts short the existence of her lord and master—by giving him poison!

Widow Johnson, at Barton-upon-Irwell, we are delighted to say is proved judicially to be a widow of the involuntary, the honourable class—pronounced, we say, innocent of the poisoning charge. The three pennyworth of arsenic which she was proved to have bought—was for rats! All honour, then, to widow Johnson!—we cast no imputations on her!

Professor Leigh, of the Pine-street Medical School, Manchester, lecturer on organic chemistry and forensic medicine, we are just as delighted to find may consider himself *inferentially* acquitted of incompetence to discover arsenic; because it is now established, by the scientific record of a British jury, that when Professor Leigh examined the body for arsenic, and could not find it, the poison might not have been there,—and that the arsenic ultimately found; when the body was exhumed, might have soaked into the body dissolved in some water which was discovered in the grave. All honour, then, to the scientific merits of Professor Leigh! Our remarks cannot be unpleasant to him!

But, seeing that a considerable time has elapsed since the first particulars connected with this extraordinary case were brought before the notice of our readers, a slight recapitulation of the same may not be unnecessary.

Elizabeth Johnson, then, a widow some thirty-three years old, did possess a husband, but, far from concentrating her affections on the aforesaid, she had been heard to express a remarkable attachment for a Mr. Abraham Hewitt's—little finger. (a) Now, this peculiar digital adoration of Mrs. Johnson seems to have carried her occasionally beyond the strict boundary of female propriety; for the evidence of another witness (Elizabeth Wood) went far to prove that Mrs. Johnson had been seen in Abraham's bosom—in other words, the witness deposed that she had seen them in bed together. Thomas Brooks, again, proved that Abraham was not backward in adoration, for he had been seen to kiss his innamorata's lips!

Truly, however much of romance there may be in the above recital, there are elements of much disquietude for a husband. But the lady's improprieties did not end here. She had been heard to indulge in the expression of sundry evil wishes and maledictions directed towards her husband; and here we would remark, that it seems judicially determined beyond power o

(a) Prisoner had told witness that she liked Hewitt's little finger better than Johnson's whole body.—(Vide Evidence of Ellen Gateley.)

controversy that evil wishing is endowed with a potency; that the arch fiend may listen to and grant the malignant prayer; for here we see an evil wish speedily followed by all the symptoms of arsenical poisoning! Strangely enough, too, the Evil One so entangled this mysterious affair in a mist of collateral circumstances, that not only was Mrs. Johnson for some considerable period subjected to the imputation of murder, but Professor Leigh—since pronounced *inferentially* a competent man—was considered for a brief period somewhat the reverse of this. On the 7th of November Mrs. Johnson purchases three pennyworth of arsenic to kill rats; and, strangely enough, on this very day her husband began to suffer from a disease precisely simulating a case of arsenical poisoning. Friends call to condole with the grieving wife, and say, "Your husband will soon be well again;" when she, with the prophetic spirit of a Delphian oracle, says, "He will die this night!" And so he does.

On the 4th day of December, the day after Johnson's death, his viscera are subjected to the chemical scrutiny of Mr. Leigh, who, on using Marsh's test, discovers a trace of something—arsenic or antimony, he thinks—which he cannot tell! This is his evidence. In the *Pharmaceutical Times* of that period we penned some strictures on this chemical examination, and on the 9th of March the body was disinterred, and subjected to re-examination by Mr. Leigh; assisted this time by Mr. Henry Hough Watson, who, at the trial, stated that he was an analytical chemist at Bolton, and had been so for fifteen or sixteen years. Had considerable experience in testing substances for detecting the presence of arsenic. Was with Mr. Leigh and Mr. Hepworth at Deane churchyard on the 9th of March. Furnished the jars for the purpose of removing portions of the body. They were well washed and quite clean. After portions of the body were put into them the lids were put on, and tied over with bladders. The substances taken were the heart and some blood in one jar, a kidney in another, the tongue and gullet in another, a portion of muscle from the right thigh in another, the intestines in another, and a portion of the liver in a glass jar. The jars were then put into a hamper, with the exception of a glass jar containing the liver, which he took home with him. The hamper was sealed by him and Mr. Leigh, and delivered to Inspector Maybury. Submitted the liver to Marsh's test, and had evidence of the presence of arsenic. [The metallic deposits on slips of glass in small glass tubes, and on Wedgwood's ware pestles, were here exhibited to his lordship and the prisoner's counsel.] That liver had never been out of his custody, except for a minute or so that the policeman held it while he was engaged in getting other portions of the body. Unpacked the hamper himself; it was precisely in the same state as when packed up and secured. Believed that the glazing of the jars would have no effect upon the various substances which were placed in them. Earthenware is sometimes glazed with lead, and sometimes with common salt; he did not know what the brown ware jars had been glazed with in which he had the substances from the body put in Deane churchyard. He detected arsenic in all the substances taken, but most in the intestines. There was some in the kidney also, and a very slight indication of it in the gullet and tongue. He used Marsh's test, which was the best for detecting small quantities. He placed the utmost reliance upon Marsh's test as an accurate one. He also used Reinsch's tests for some portions of the intestines. He burnt some of the gas produced by acting with Marsh's apparatus in the bulb of an oxidizing tube, and he got some water condensed in the bulb, which he found to be arsenious acid on trying it with ammoniacal nitrate of silver, which produced a yellow precipitate, and by ammoniacal sulphate of copper, which produced a green precipitate. He also tried it with sulphuretted hydrogen, which produced a yellow precipitate. He tried experiments with the metallic deposits, by applyin

chloride of lime to those obtained by Marsh's process of glass and porcelain, which removed them. That, together with the other results, indicates that the metallic deposit is not antimony, and that it is arsenic. From his own experience and knowledge he should say it was arsenic, though he cannot say that chloride of lime will not remove other substances besides arsenic. It will not remove antimony. He also exposed some of these metallic deposits on glass to a temperature ranging from 355° to 365°, by which they volatilized and left the glass; this is another proof that the metal is not antimony, but arsenic; antimony does not volatilize at the temperature mentioned, but remains permanent, while it is one of the properties of arsenic to become volatilized at that temperature. Some of the slips of copper on which he had got a strong steel-like metallic deposit by Reinsch's test were exposed to heat in a glass tube, and the metallic deposit became oxidized, and deposited itself higher up in the tube. That, oxide afterwards boiled in some distilled water, and tried again with the ammoniacal nitrate of silver, ammoniacal sulphate of copper, and sulphuretted hydrogen, and they gave the same precipitates as before, from which he concluded that the water contained arsenious acid. He had no doubt that the body he saw exhumed contained arsenic. He cannot say how much—perhaps not more than a grain, if so much, in the nineteen ounces of intestines he operated upon.

It seems, then, that Mr. Watson most satisfactorily proves the presence of arsenic in the disinterred body in the beginning of March, although Mr. Leigh could not do so on the preceding 4th of December! The learned judge's (Alderson) charge to the jury contains some significant passages. He commented particularly on the circumstances under which the arsenic had been detected; he said Mr. Hepworth, the medical man in charge of the case, had admitted he was not so much a chemist as a surgeon; and that, of the two medical men who performed the first analysis, Mr. Leigh should have been the more competent; he was a lecturer on medical jurisprudence; and if, on the first examination of the body before interment, he was not satisfied whether arsenic was present or not, he ought not then to have stopped; certainly that was the most likely time to have found the arsenic if any was present. On this occasion, remarked the learned judge, he did not detect anything which he was sure was arsenic; and it was not till the second examination of the body, after it had been exhumed, and when he had the assistance of Mr. Watson, the chemist, that he was sure of the presence of arsenic (this was Mr. Leigh against Mr. Leigh). If, before the body was buried, he was not satisfied, nothing could have been easier than to have gone to the coroner and told him so; when, undoubtedly, he would have had an order given him to go and obtain such other parts of the body as he might require. Mr. Leigh says Mr. Watson made the chemical examination after the body had been exhumed, and we have heard (said the judge) that that skilful chemist tested his distilled water, and all the other ingredients which he used, and the vessels in which he operated on the various parts of the body, to be sure that they were quite pure, in order to preclude the possibility of arsenic, by such medium, from entering into the parts he operated upon; but the quantity of arsenic which Mr. Watson found was but very small, not more than a grain, if so much, in the nineteen ounces of intestines; and, as the grave was wet, may there not be a possibility of this small quantity of arsenic being derived from water which had drained into the body out of the soil of the churchyard? It would have been more satisfactory if the arsenic had been detected in the first instance, instead of after it had been lying for three months in the ground. His lordship drew particular attention to the statement made by Mr. Leigh, that in cases of poisoning by arsenic white or yellow spots are usually found on the coat of the stomach, and that in this

such were not in the stomach when the examination was made only a few days after death, but there were red patches. He advised the jury to weigh carefully the evidence bearing upon the purchase of arsenic by the prisoner, and that also which tended to show a motive for her making use of it in order to remove her husband. Her conduct during the illness was not thought inconsistent with the conduct of a wife attached to her husband. The questions for the jury to decide were these,—Were they satisfied that the deceased died from the effects of arsenic? Were they satisfied that the prisoner bought the arsenic just before the illness? Were they satisfied that she had a motive for getting rid of her husband? And was her conduct such during his illness as to lead them to a conclusion that she administered the poison to him? If they were of opinion that he died from arsenic, then the charge against the prisoner would become a serious one for their consideration.

We need not tell our readers the result. The jury acquitted Mrs. Johnson, because, in their opinion, the arsenic found by Mr. Watson had percolated into the viscera of the corpse since interment. Thus we see justice *has been done*, and all parties have gained. Widow Johnson has gained her liberty; toxicologists have gained most peculiar information; and Mr. Leigh has gained an inferential verdict in favour of his competency to undertake a chemical analysis. This inferential verdict was no less than the scientific character of this distinguished lecturer on forensic medicine required.

MISCELLANEOUS CORRESPONDENCE.

HOMŒOPATHY.

DR. HILBERS *versus* DR. ORPEN.

[To the Editor of the Medical Times.]

SIR,—I must beg the favour of your inserting the following observations on Dr. Orpen's last letter. We now see that he has entirely shifted his ground of attack on homœopathy and the homœopaths. In his first letter he stated that "the whole of our statements, practice, and books, was a system of enormous lying and deliberate humbug of the public, for lucre." Why? Because, forsooth, he could not produce those effects with the infinitesimal doses which Hahnemann and the homœopathist, assign to large or even poisonous doses of the same substances. I trust that I have already said enough to convince all unprejudiced persons of the injustice and illiberality of this accusation and, therefore, I shall say no more on the subject. But Dr. Orpen must not forget that it is a dangerous thing unjustly to tamper with the honour and integrity of others, for he who wantonly does so must of necessity seriously compromise himself.

In the letter now before us, he endeavours to prove that the infinitesimal doses are insufficient to cure disease. As I have again and again said, I do not mean to attempt to prove the contrary although I myself am fully satisfied, and verily believe, that they are amply sufficient. The extent of my ambition is to induce others to submit them to the same ordeal that I have done. I shall, therefore, only observe, in the words of Hahnemann, that, "if he who calls himself a seeker after truth will not make his search where alone truth is to be found, and that is in experiments, truth must remain undiscovered. It will not be got at by means of the multiplication table." The only deduction which can be attempted to be drawn from the abstract calculations of Dr. Schenk is, that matter will not affect the animal fibre, except when applied to it in bulk, or in a concentrated form. This, as I before showed to all orthodox physiologists, is manifestly not true, because we know innumerable instances in which matter *does* powerfully affect the organism in quantities inconceivably minute. The experiments of Spallanzani showed

that the 2,994,087,500th part of a grain of frog's spawn was capable of impregnating the ovum. The cool way in which Dr. Orpen accuses Bell, Muller, Carpenter, and, I believe, all other physiologists "of repeating only a common error," is very amusing. I must, however, leave your readers to decide between this gentleman and these eminent philosophers.

I shall now very briefly notice some of the other arguments contained in this letter against the homœopaths and their system.

First, then, as regards the Liverpool Dispensary, I stated that the average weekly attendance of patients now amounted to 300. Away goes Dr. Orpen for the reports, and finds that there have been only 10,240 patients admitted in the four years during which it has been established. Now, he has indeed discovered a mare's nest: my own words condemn him. How is it possible that, if 300 patients are *now* prescribed for weekly, only 10,240 should have been admitted in four years? I should have imagined that it would have required no great stretch of ingenuity to solve this problem. I would, however, suggest to him the idea, that it is more than probable that the weekly attendance has greatly increased since the year 1842, when the institution was first opened; and that, perhaps, in the first week the numbers, instead of 300, were under 30. Could not the discrepancy be fairly accounted for in this way?

2. Now, another wonder appears. One of the Liverpool homœopathic physicians has actually committed an error in diagnosis. This, indeed, is a powerful argument against homœopathy! It is true, that a greater disease has been mistaken for a less, which is rather unfortunate. With all respect, I would put it to Dr. Orpen's conscience, whether he himself has never fallen into error as to the nature of a disease; but would he like to be considered dishonest on this account? I wish I could say that I had never done so; and yet I confidently hope that my professional brethren will not condemn me because I make this confession. I could give Dr. Orpen the particulars of a case in which one of the ablest surgeons in England mistook sciatica for hip-joint disease; and yet I would defend this gentleman's honesty as I would my own.

3. He next favours us with one of his sweeping assertions, unsupported by a single jot or tittle of evidence. He says that we grossly exaggerate the cases we are called on to treat, and that the report of the Vienna Homœopathic Hospital is greatly falsified. Let him bring forward any reasonable evidence to prove this if he can, and I will meet him in the best way I am able; but, if he cannot, I for one unhesitatingly assert that the charge is false, and the mere baseless fabrication of his own disordered fancy.

I must notice one other of his arguments, and then I shall have completed my unpleasant task. During the last two years, it seems that Dr. Orpen has known of three cases which "have been killed by homœopathy." During the same period I have known at least three dozen persons who have been killed by allopathy, if the word "killed" means that they died under allopathic treatment. Such an argument as this would be all very fair if we contended that homœopathy and immortality were synonymous terms; that under our system patients never died; that, in fact, we were able to secure them from the ordinary fate of mortals. As, however (to the best of my belief), this has never yet been done, and as we at present merely claim superior powers over disease, and not a complete and irresistible power over death, I humbly submit that the death of Dr. Orpen's three friends, under the homœopathic treatment, is no proof of homœopathy being false, or of our being cheats and impostors.

I have neither time, patience, nor inclination to notice further such arguments as these. Indeed, I think that an apology is due to your readers for having apparently doubted their penetration by attempting to refute them. I cannot believe that the enlightened members of the medical profession, who are accustomed to weigh evidence, will attach more importance to

them than they justly deserve. In future, therefore, I shall entirely abstain from trespassing on their attention, unless I see some better reason for doing so than I can discern at present. Besides, I manifestly labour under a great, almost an insuperable, disadvantage. It is easy to frame an accusation (such as that respecting the Vienna Hospital, for instance) in half a dozen lines, whereas it would take almost as many columns satisfactorily to refute it.

Before I conclude, I must once more beg most respectfully to urge on the profession the evident necessity there exists for investigating this subject further. The field is open to all; there is nothing required but a little patient experiment to solve a problem which has puzzled the medical world for half a century. If homœopathy is false, nothing else will so surely and speedily overthrow it. If it is true, nothing will be so likely to establish it; and I feel convinced that, if the profession were once assured that such was the fact, no considerations of personal inconvenience would hinder their gladly availing themselves of the advantages it offers them.

HOMŒOPATHY.

[To the Editor of the Medical Times.]

SIR,—There are a class of men existing and moving in the medical world for whose natural talents and amiable dispositions I entertain the highest respect, derived from a personal acquaintance with some of them. Sincere and honest, but credulous and erratic, they are liable to be driven about by every wind of new doctrine or heresy that may blow upon them.

One was a highly-estimated anatomical preceptor of mine. His prospects then promised well, and would undoubtedly have been realized had he been content steadily and perseveringly to "bide his time"; but he wandered from established medical science into the perplexities of mesmerism and from one watering-place to another (a well-known migratory propensity of the genus), and at last launched on the ocean of hydropathy, where I greatly fear he will be drowned.

Another, when I was a student in the metropolis, was a promising physician, a member of the Westminster Medical Society, where I have once and again witnessed the coruscations of his intellect. He, too, left the beaten path, already well trodden by his professional fathers, pursued a similar course to that of my friend the anatomist, and is now lost in the labyrinth of homœopathy.

For such men (and for the unwary) my communication on homœopathy was chiefly intended. I wished to point out to them, that in their ardent search for truth they were actually stumbling over her. I suggested that they should examine whether their *similia similibus* be of the pure flame of Truth, or a deceiving *ignis fatuus*, likely to lead them into the quagmire of disappointment and disgrace; that the law they sought would probably be found internally, and not externally—latent and acting, or ready to act, and not needing to be introduced; that it was highly probable the agents of *régime* and *hygiène* were those to which they were altogether indebted for any success which might follow their efforts.

I am glad to have attracted the attention and inquiry of one of these worthy "Truthseekers," of whom, however, it may be feared that, "slight as may be his experience in the science (as he will have it) of homœopathy, he is already an adept in the art to which that system speedily leads—viz., the art of mystification, or the science which teaches the best mode of throwing literary dust in the eyes of readers." But I would ask my truth-seeking friend, if to disregard the substance, to set aside the facts, to dwell upon mere hypotheses, to carp at a figurative representation, to make quotations without their contexts, to cavil at a grammatical construction, be means likely to open to him "the door of the Temple of Truth" which is effectually

guarded," not only "against the footsteps of prejudice, bigotry, and intolerance," but also of capriciousness, quibbling, and cavillation.

A full and fair reply to the observations of "Truthseeker" on my friendly communication "on homœopathy" might be made by its reiteration—*verbatim, literatim, et scribatim*. But, as I intend briefly to show the capricious character of his remarks, I will content myself with a few repetitions, embodying the main points which I am anxious to keep before the mental view of our readers, as forming those upon which homœopathy will ultimately stand or fall in the estimation of the simple and sincere searchers for truth—those which "Truthseeker" has completely overlooked; fixing his undivided attention and twisting ingenuity upon those points, in the defence or support of which I am not desirous to give much consideration.

One proposition I hold is this, "The patient's diet being submitted to proper regulation, I am prepared to prove practically and ocularily that any case, curable as it is supposed by the administration of homœopathic medicine, is equally curable without the exhibition of an atom of medicine of kind." If "Truthseeker" consider this "a side blow at allopathy," so let it be; I neither wished, nor intended, to defend allopathy in the character that term indicates. Legitimate or established medical science is not *allopathy*. "A disease of the same nature, acute or chronic, existing in two or half a dozen patients, of like age and circumstances, subjected solely to a proper arrangement of diet, air, temperature, and exercise, shall disappear as quickly as when homœopathically treated—in fact more quickly, if the practitioner have a better knowledge than his opponent of the virtues and influences of those hygienic agents." If this stand the touchstone of experiment, as I am fully prepared to prove, or to try, then of what value are homœopathic drugs? Let it be put to the test; let it be subjected, as "Truthseeker" proposes, "to a tribunal of men of acknowledged abilities." Let the so-called facts, or, more properly, *fictions* of the system be first subjected—then its principles—"to a fair and impartial analysis, and judgment be pronounced accordingly." For I still hold and believe the assertion, that "facts are the only basis," or, I would say, to meet "Truthseeker's" sensitiveness as to grammatical accuracy (not my own sense of the elegant and the concise), the only *sure foundation* "of accurate knowledge." But facts alone are not sufficient, and unless they be collated, and their relations to each other and to general laws be deduced, by a careful induction, they lose the greater part of their value, and become, to use the apposite illustration of an able writer on political economy, little better than the undigested crudition of an almanac-maker, and afford no means of judging of the truth or falsehood of a principle or rule of practice." (a) "But I should like to know of one well-authenticated, undoubted, and modern or recent instance in which"—to meet "Truthseeker's" translation of Hahnemann—the "usual allopathic doses," in their effects, confirm Hahnemann's provings and statements; or in which that experiment has been satisfactorily repeated and confirmed which Hahnemann tried on himself when, as Dr. Hilbers gives it, "the thought occurred to him that it would be highly interesting to know how quinine," so noted in its efficacy in the cure of ague, would act upon himself. He at once tried it, and a febrile attack was the result; it produced in him what it cured in others; it brought his bodily system into the state out of which it removed others already in it. To his inductive mind this was clue enough to the principle of *similia similibus curantur*." "How we apples swim!" or, in my own words, "Show me any other phenomenon said to arise from the use of homœopathic medicine; but let that result be clear, definite, direct; not occult, not needing to be deduced or made to appear: then I shall consider

it a signment worth attention, though requiring the recurrence of the same results under the same circumstances, nine times out of ten, or ninety-nine times out of a hundred, to establish the facts beyond all question." I have often been amused by hearing a medical friend, possessed of quick mental perception, at once disperse some *wonderful* narrative, by saying to the relater, "My dear Sir, I question the facts." So, in spite of the opinion of "Truthseeker," in his own estimation, "an unprejudiced and independent reviewer," "that in his judgment the propositions of Dr. Hilbers have not been at all affected by the arguments of his opponents," I say Dr. Hilbers has never proved his propositions. The fundamental facts of the system are not confirmed. I question its facts. And it should be remembered that Dr. Hilbers first and spontaneously came forward to "indoctrinate" the readers of the *Medical Times* (see vol. xiii., page 79) in the art and mystery of homœopathy.

Another point I reiterate and maintain is, "In proof of the utter nullity of homœopathic drugs, I will engage to produce" many cases of disease of the character I have before enumerated which have been cured without the administration of a particle of medicine—to illustrate and confirm the first proposition I have reiterated; and, lastly, I can relate well-authenticated cases of the dangerous nature of homœopathic dogmas in cases of acute disease.

I shall now, in a few words, dispose of "Truthseeker's" cavillings. "He should at least have taken better care to instruct himself" that "analogy in philosophy denotes a certain relation or agreement between two or more things which, in other respects, are very different." He should also have known that "integral, or integrant, is an appellation, in philosophy, given to *parts of bodies* which are of a similar nature with the whole."

As to the term *vis medicatrix*, I have anticipated many of his remarks by the passing observation (*Medical Times*, vol. xiv., p. 330), that "homœopathy, though it passively permit many of its confiding but deluded victims to perish by doing too little, will equally teach the thoughtful practitioner to confide in hygiene; to give less physic in some cases, to trust more to the *vis naturalis*, not always, by-the-by, the *vis medicatrix*." Unite this passing remark with that made in my last communication. This law, the *vis naturalis vel medicatrix*, "acting not upon matter merely, but upon *living* matter, its phenomena are essentially connected with life itself; and, until the properties and contingencies of life be understood in their full extent and bearings, its extent and power will remain undiscovered," and we have a text upon which I shall be glad to hear "Truthseeker" expatiate to his heart's content. There is an illustration of his which somewhat aptly illustrates my figurative representation of the *vis*, viper-like, inflicting a fatal wound upon itself. In peritonitis, we have not the *vis medicatrix vel naturalis*, but the *vis abnormalis vel morbida*, not probably "pouring into the membrane an excessive quantity of blood," but permitting its excessive accumulation. Then comes in the *vis medicatrix vel naturalis* to the rescue. Serum passes out of the vessels by exosmosis into the peritoneal cavity, to be removed by the action of the absorbents. We imitate the efforts of the *vis* by the application of revulsives and derivatives, and by exciting the absorbents. We, perhaps, succeed; or the *vis morbida* being more powerful than the *vis naturalis*, although assisted by the efforts of orthodox science, causes us to fail. The law, "Dust thou art, and unto dust thou shalt return," reigns and forms a contingency which renders the *vis medicatrix* not a law "as unfailing and unchangeable as the laws which govern the phenomena of inert matter"; and perhaps we injudiciously and erroneously echo the "affirmation of the late Dr. J. Johnson, that in the exhibition of remedies he believed he had done more harm than good."

The doctrine of idiosyncrasy is certainly of a deeply interesting character, and "relates so particularly to peculiar tempers and dispositions

not common to others," that I do think its further study is highly calculated to shed light upon the strange vagaries and hallucinations of the advocates of homœopathy.

A. C. CROSS.

Grosvenor-street, Manchester, April 12.

[We have thought it but an act of justice to our respected correspondent to insert his letter, and we must now decline opening our pages for further controversy on the subject.—Ed.]

PRACTICE v. PRECEPT.

[To the Editor of the Medical Times.]

SIR,—The manly independence and unflinching consistency which characterize the conduct of your Journal I have hitherto been content to contemplate and ruminate upon in silence. Fain would I now indulge my mental *siesta* uninterruptedly, and little amiable do I feel at having my reverie disturbed by such a flagrant contrast as I have this day been betrayed into witnessing—a contrast which would move even stones to murmur. A sorry scribe, I entertain a wholesome aversion to writing myself down an ass; excuse me, therefore, if I ask the most obscure corner of your forthcoming number wherein to prefer my plaint. As the victim of seduction, of a misplaced confidence, I would seek, but dare not ask, your pity. You might justly reproach me with a hint that—

"It will be off with the old love,
Before you be on with the new."

To be candid, Sir, misled by syren signals, I have surrendered myself to the perusal of a contemporaneous print for a few weeks past, "hinc illa lachrymæ."

Quackery is avowedly the bane of my unhappy profession; flatulent denunciations of its mischievous maraudings have appeared, a deadly war of extermination has been declared, and the heads of the profession have been called upon publicly to lend their aid by disclaiming, or otherwise, the surreptitious use of their names in connection with certain quack announcements: Morrison, the mesmerists, Holloway, the hygeists, homœopaths, hydropathists, Dalbys and Dinneford's, Lococks and lollipops, have been apparently crucified, hashed, grilled, deviled, and dished up with a piquancy of style that might satiate a salamander, in a profusion that might mock the maw of a cornucopia, and provoke this glutton to a Dandonian feat of self-indulgence, especially as Cockle's antibilious pills stand only a notch or two down in the bill of fare. Judging from the crafty records I had been perusing, the work of annihilation seemed all but complete, in the fond belief that the time was fast approaching when a quack would become a *rara avis*, like as a black swan or the tabulous phoenix, in my simplicity I had culled the laurel and twined it in a wreath to deck his brow, when the "exterminator" should be proclaimed throughout the land.

"Vie misere mihl! quanta de spe decedit!"

It was all a dream, a cruel delusion, which, reaching its climax, has exploded in my hands this blessed Saturday, the last that ever was. Doting, as usual, I seized with avidity the "—" (odious thing, "I can't say the word if I try"); but coy, as the American maid who describes the male of the poultry-yard as a "rooster," I would suggest that I seized the "*steam*," plunged into a bloodthirsty reflection on the mangled remains of the Cronins, Coffins, Flitcrofts, et id genus omne, till, as my glutton eye wandered in search of a fresh whet, the veil was suddenly ript from before it. Was this a dream? or that mesmeric manifestation, "clairvoyance"? If the latter, what will it not see through? In rampant and unblinking quackery out-Heroding Herod, the serpent, which had insinuated itself into my bosom under the guise of a scientific publication, was clutched convulsively in my hand, and stared me in the face, throwing back as from a mirror, into my very teeth, the humili-

(a) Quotation by Mr. Noble from Dr. A. Combe.

liating portrait of an unmitigated fool. I, who claim to be a scientific member of a liberal profession, caught myself conning "Molly Coddie's Journal."

"Garry I believed thee true,
And was blent in thus believing."

Should I be preserved to my friends, and restored to my position in society, after such a narrow escape from scientific suicide, I do most unconditionally promise henceforth and for ever to abandon all M.P.ical medical literature, keep myself distant as Indus from the pole, stand off as far as "Mullin's Physics."

What has thus disturbed the equilibrium of my philosophical teapot? You might well ask, seeing that, midst shame and confusion, I have neglected to explain.

My nerves are so shaken I have barely energy to point to page 423: there it was I saw, or thought I saw, under the attractive heading "MEDICAL NEWS."—"COLLEGE FELLOWS," the very counterpart of an announcement which in your journal had been assigned its proper place, the *advertising columns*. Yes, there in the garb of medical news stood the *ipsissima verba* of a quack advertisement, which transplanted to so genial a soil, and under such a sunshine, had actually regenerated and wagged with impudent defiance that venomous tail of which you, even as an advertisement, had prudently docked it, sting and all.

The devil is the father of all mischief, and doubtless this black job will be saddled on one of his imps. How could an *infernal minor* be expected to diagnose as *hideous* in another that caudal continuation so ornamental in *propria persona*, and which, bearing only a sky-blue tint upon the *ipse dixit* of his parent, the world has been content to recognise as the line of demarcation between *neat* and *gaudy*. Far be it from me to plead in aggravation of punishment to this delinquent. I address myself to you, Sir, in a spirit of friendship now, to warn you against betrayal by any such hopeful seion of the house of Beelzebub. Once you unwittingly allowed a back number to slip out of your office; you personally paid the penalty; but should you permit such medical news to slip into your columns, Fate only knows upon whose devoted head the penalty might descend.

Little did I deem, when listening to Mr. Slangwallper Lawrence, fifteen months ago, that I should be found joining in the response, "true, oh King!" but, when newly-fledged members of a higher grade, to wit, fellows, are to be found wallowing in the polluted mire of the filthiest and deepest abyss of medical quackery, then do I proudly acknowledge my error, and declare that to *extra-ordinary* emergencies such as these, the simple members are utterly incompetent. Thus is the dignity of the College upheld with a vengeance. I ken not what kind of document might be issued to distinguish a "fellow" from the common herd; nor the decorative design which might have been selected as a head-piece. If the furnishing a prize motto is still matter of competition, be so good as register in my name, "Quo lapsus—quid feci."

Can you inform me, Sir, at what respectable society in London the following proposition would be fairly discussed? By how much were Messrs. S. and R., on retiring to bed as *fellows* of the College one Wednesday night, better surgeons than they were on awaking as simple members on the morning of the same day?

I am, Sir,

Your obedient servant,

O TEMPORA! O MORES!

Member of the Royal College of Surgeons of England, and Odd Fellow, B.O., Manchester Unity.

April 17.

P.S.—Great discoveries have been stumbled upon by accident; possibly my remarks might throw a light on the periodical complaint of your contemporary's oppressive weight of correspondence in the quackerie region. A knowledge of disease is half its cure.

THE PONTYPOOL SULPHURIC ACID POISONING CASE.

Hannah Thomas, 26, was indicted before Mr. Justice Maule, on Monday, the 12th inst., for the wilful murder of James Thomas, her illegitimate son. The case excited much interest, and the court was crowded throughout the whole of the trial. The prisoner wept during the whole of the proceedings, and seemed to feel her painful position. Mr. Greaves and Sir T. Phillips conducted the prosecution, and Mr. Cooke defended the prisoner. She pleaded "Not Guilty."

Mr. Greaves, in opening the case to the jury, said, in any case where a jury were called upon to investigate the circumstances of a person's death when the crime of murder was involved, it was a matter for their most serious and attentive consideration. But when the case was the death of a child at the hands of its mother, he thought they would agree with him its claim to their attention was much enhanced. This, unfortunately, was the nature of the case they were now called upon to investigate.

Ann Perkins was the first witness examined. She deposed that she was the matron of the Pontypool workhouse; knew the prisoner at the bar; she (Thomas) was admitted into the workhouse on the 3d of December; was then pregnant; was delivered of a male child on the 16th of February; on the 26th of February she was going her round, and went into the lying-in-room, where the prisoner slept; it was between eight and nine o'clock at night; the prisoner was in bed; asked her how the child was; she said it was poorly, and had been so all day, and would not take rest; she thought the child had fits. Saw nothing in the appearance of the child to induce her to suppose the child was ill. Margaret Thompson, a pauper, slept in the room. She acted as a nurse. Saw the child next morning; the child was then dead. Its lips were black and scorched. The bottle produced was kept in the women's kitchen. The teacup produced was similar to one which was near to the bottle. They both contained a lotion for application to children's scald heads. There is a regulation in the house that no person confined in the lying-in-room or the sick ward shall leave those rooms without the permission of the master. This was known to the prisoner. I informed her of it. The dining-hall is between the kitchen and the lying-in ward, and the door was kept locked.

Moore Matthew Perkins, the master of the Pontypool workhouse, and the husband of the last witness, deposed that on the morning of the 27th of February he was called for to see the child of the prisoner; went to the lying-in ward, and found the prisoner there; she was in bed; appeared to be pretty comfortable; the child was lying dead alongside of her; examined the child, and found no marks of violence on it; afterwards saw it in the dead-house, and there observed that the lips were scorched and burnt; fetched the medical officer, who also made an examination of the child.

Mary Miller deposed that she was a pauper in the Pontypool workhouse; that the bottle and cup produced contained a lotion which was given to her for her children's heads; they had the ringworm; the doctor sent the lotion; recollected the prisoner sitting beside her while she was dressing the children's heads; left some of the lotion in the cup; should think about two or three table-spoonfuls; left in the cup a piece of rag with which was applied the lotion; after having done with the cup put it back in the window in the kitchen on the right-hand side of the yard-door; went into the kitchen a second time, about eleven o'clock, and saw that the bottle and cup had been moved to the middle of the window; there was no lotion then left in the cup; the rag was there; stripped the prisoner's child when it was dead and laid out the body; there were no marks of violence about him, excepting in the lower part of the lip, which appeared to have been burnt; asked the

prisoner what was the matter with the child's mouth; she replied she did not know; the clothes produced are those which she took off the child; Charlotte Harris, Ann Lewis, and herself, washed the clothes, and among them the clothes worn by the child; all engaged noticed that on washing them they tore in a similar way to that in which her children's caps did when they were washed; there were stains upon the clothes like yellow, the same as was on her boy's cap; saw the shirt in the evening; it was torn in a similar way; the napkin with which the prisoner wiped away the froth from the child's mouth was similarly torn.

Cross-examined: The mark on the lip of the child was red and about the size of a pea; the place where she left the bottle was about a yard and a half from the ground.

Jane Rees, a girl fifteen years old, deposed to seeing the prisoner in the kitchen two days before the child died; she saw her near the window, and heard the rattle as of a cup; there was a bottle on the window at the time; after dinner she was in the lying-in-room; she there saw the baby who was sick; what she saw it throw up was black and red; the prisoner said there was nothing the matter, and she should be glad if the child was to die.

Ann Lewis, a single woman, living in the Pontypool Union, also saw the prisoner in the kitchen; prisoner stood near the window; the bottle and cup were there, and she saw the prisoner with the cup in her right hand; when she went in the prisoner pushed the cup towards the bottle; the baby was crying. This witness also saw the child throwing up some yellowish stuff.

David Conway Evans, an apprentice to Mr. Lawrence, surgeon, of Pontypool, mixed up the lotion contained in the bottle. It consisted of one part of sulphuric acid to twenty-nine parts of water.

Mr. Cossens, surgeon, of Pontypool, was next examined. He said: I attend the union workhouse as a medical officer; the child of which Hannah Thomas was delivered was a very fine and healthy child from its birth; I saw it dead on the Saturday. I first examined the body externally, but could find no marks of violence on it, nothing more than an abrasion on the external border of the lower lip; I inquired of the prisoner the cause of her child's death, as far as regarded the symptoms it exhibited; she told me the child had had catchings and jumpings, which I thought was the result of fits or convulsions; I asked her whether it had vomited; she replied that it had not; she also said that she had given the child nothing but the breast. I repeated my questions; but she replied in the same way. I asked her why she had made no communication to the master relative to the child's illness; she said that she had told those around her. I made no further investigation that day. Prisoner asked me whether she might leave on the following Monday; I said, "No; since we are not perfectly satisfied as to the death of your child." On Tuesday I opened the body; I examined the mouth, the throat, the passage to the stomach, and the stomach itself, and the small intestines. The mouth was in a very healthy condition, but in the back part of the throat the mucous membrane was corroded and detached in several places; the same was the case down to the stomach; the stomach was slightly inflamed in places; the mucous membrane was softened so much that it could easily be removed by being scraped with the nail; the small intestines were also corroded, but in a less degree than the stomach; I tested the parts with litmus paper, to ascertain whether there was any acid in them; the reaction on the litmus paper was very slight; acid would not, in the natural state, exist in that part which lies between the throat and the superior orifice of the stomach; I believe acid might exist in the stomach from natural causes; I also examined the lungs, the liver, and the brain; I found them congested; the internal portion of the brain, however, was comparatively healthy; the sur-

face of the brain seemed congested. I was led to believe, at first, from my own examination, that intense inflammation was the cause of the corrosion observed.

Sir Thomas Phillips: Now, Mr. Cossens, assuming that the child was in a healthy state on Thursday morning, in your judgement could the state of things which you found, and which you have described, have made their appearance on Saturday evening from natural causes?—It is not at all probable.

His Lordship: You are not asked whether it is probable or not. The question is a plain one, and it is a wonder you cannot answer it directly. Could those effects have been produced in this short time, or could they not?—In my opinion they could not.

Sir Thomas Phillips: But it might have been produced by the administration of sulphuric acid?—Yes.

How much would have been requisite to have produced those effects?—A tablespoonful would have been enough on an infant of that age. The burning of the lip and the frothing at the mouth would have been produced by the same cause. I have examined the clothes; the marks on them, and the condition in which they appear, are likely to have been produced by acid, such as I have described; the first effect it would have would be to produce a stain, and when put in water and washed it would be very likely to produce holes similar to that produced; on coloured linen it generally produces a red stain; I have tried acid diluted to the same extent as this is on some linen, and have found the effects to be such as I have described, as far as I can judge; I analyzed the contents of the stomach, but could find nothing therein to explain the cause of death; the vomiting would account for the absence of acid in the stomach.

Cross-examined by Mr. Cooke: Have you told the whole truth, Mr. Cossens?—Certainly, so far as I know.

Upon your oath, sir, were not the appearances you saw likely to arise from natural causes?—Not very likely.

Could the state in which you found the stomach, and intestines, and other parts, have been produced by natural causes?—No; it could not.

Were you able to find in the stomach and intestines any trace of sulphuric acid, or any other deleterious substance likely to cause death?—No.

Why did you not tell us that before?

Sir T. Phillips: I did not ask him the question.

Mr. Cooke: I understand you to say that there was a slight abrasion on the lip?—I did.

Now, my learned friend spoke of excoriation; what is your opinion on those two words—are they of a different meaning?—The difference is little.

As a highly-scientific man, do you say that you know no difference between abrasion and excoriation?—No; there is none.

Very well, sir. Would an ulcerated nipple in a mother produce any effect on a child?—Yes; it does sometimes. I don't suppose it always does.

Did you examine the poor woman to see whether she had a nipple bad or no?—I did not.

Is not froth at the mouth a natural result of convulsions?—Yes; it is sometimes produced by convulsions.

Is it not a natural result, I ask?—It is.

Supposing the child to have died of convulsions, would you not expect to find, on examination, its lungs and the vessels of the brain congested?—Yes.

And in the case of the blood being thrown to the brain the remaining part of it might be healthy?—It might.

Do you not know, Mr. Cossens, that a person apparently well might be, from convulsions, perfectly dead in an hour or two?—I do.

Am I rightly informed by the medical books I have looked at that illegitimate children

are larger in growth than legitimate children?—Really, sir, I cannot answer that question.

Is it not a fact that full-grown children more frequently die suddenly than those who are more weakly?—I don't know.

Do full-grown children suddenly die in infancy?—They do.

From convulsions and other causes which the medical science cannot explain?—Yes.

Do you happen to know that sulphuric acid is used in bleaching cloth?—I am not prepared to answer that question.

Did you never hear of its being used to take iron moulds out of shirts?—No.

Do you not know that sulphuric acid is used to discharge the colour out of cloth?—I am not prepared to say; it may be the case.

When you examined the child's mouth, you could find no clue to the child's death; there was no ulceration?—No.

I take it, Mr. Cossens, that an infant ten days old would be a considerable time in swallowing sulphuric acid and water?—Perhaps it may be so.

Why, sir, sometimes when you give sugar and water to a young baby ten days old it would refuse it, will it not?—Yes.

Were you not surprised, then, to find the entire absence of ulcers from the mouth?—I was rather surprised.

It had been suggested to you that it was supposed that the child had died from poison?—It had.

Sulphuric acid is extremely sour, I believe, and the taste very disagreeable, worse than vinegar?—It is.

It is, in fact, diluted oil of vitriol?—Yes.

When did you first learn that Mr. Brew, your assistant, was coming here as a witness?—On Saturday last, I think.

Did you send for him?—I did not.

The witness then, in answer to his lordship, said that if acid, as strong as that contained in the bottle, had come in contact with the mouth of the child it would have produced sensible and visible effects. Unless it was poured down the throat without touching the mouth, he could not account for the absence of any effects on the mouth.

Charles Brew: I am a surgeon, and assistant to Messrs. Lawrence and Cossens; I have been in practice since August, 1842; my practice has been very extensive. Mr. Cossens showed me the passage which leads from the mouth to the stomach, which he had taken from the child, and some portion of the intestines; in these parts I observed the almost total destruction of the lining or mucous membrane; it was destroyed by its removal from the subjacent parts; it was what we call corrosion; it was not removed by inflammation arising from natural causes, decidedly; I cannot say whether it was taken off by the surgeon; I am decidedly of opinion that it was removed by some corrosive irritant; diluted sulphuric acid is an irritant that would be likely to produce those effects; I prescribed the mixture in the bottle produced—sulphuric acid and water; a tablespoonful or less would produce the effects. In my experience as a practitioner, and from my knowledge derived from reading and other sources, I decidedly do not believe that any natural causes have produced the appearances; an ulcerated nipple on a mother's breast would not produce such effects on a child, nor convulsions, nor sudden fever.

Cross-examined: I did state that the detached parts of the mucous membrane might have been severed by a surgeon's knife, but that was a mistake; I now say quite the contrary; a surgeon's knife would injure the muscular fibre beneath; I was first spoken to about coming as a witness yesterday; the examination of the parts of the body was made by me before the coroner's jury delivered their verdict.

Mr. Cooke: Having mentioned your great experience, perhaps you can tell us whether a young infant put to swallow vinegar would not resist it so as to cause some portion of it to re-

main in the mouth?—It might do so; it depends entirely on the strength of the vinegar.

His Lordship: Take the weakest kind of vinegar?—I think it would.

Have you any doubt about it, as a scientific man, with all those years of experience?—No.

Do you consider that the mouth is less sensitive than the throat?—The mouth is less sensitive.

The learned counsel for the prosecution said this was the conclusion of their case; but, with the permission of his lordship, he would recall Mr. Cossens and put to him one question. It was this: Did Mr. Cossens remove the mucous membrane with a knife?—Mr. Cossens: Decidedly not.

Mr. Cooke then addressed the jury for the prisoner. They might suppose that a poor woman just come from a parish workhouse had but very little means for employing an advocate to appear in her defence. She had, however, to thank some humane and considerate persons, who were not willing that she should stand her trial here to-day with all these prejudicial circumstances against her with what they were pleased to consider the benefit of counsel. He did not appear before them, therefore, instructed by an attorney, and with all the advantages which were generally enjoyed by barristers in such cases. It was usual in cases which involved the crime of murder to endeavour to ascertain a motive which might have induced a party to commit an offence so unnatural. Love of plunder, desire of revenge, were frequently brought forward to satisfy a jury in this particular; and, in cases where a mother was charged with the destruction of her illegitimate offspring, the inducement might be found in the endeavour to conceal her shame. This, however, could not be said to apply to this case. There was not only no concealment attempted, but the mother came into the house supplied with clothes for her child; and, not only this, but up to the very hour of death was she proved to have exhibited the utmost anxiety, solicitude, and affection. There was but one witness—he wished he could pass over it without remark—who had attempted to insinuate that the mother had acted indifferently in the matter. Only Mr. Perkins, the turnkey, the policeman, the quondam West India something, had said that the prisoner appeared pretty comfortable when he came in. They had the evidence of the pauper that slept in the room to show to the contrary. He remarked on the impropriety of a man visiting the lying-in-room, and of leaving poison in a pauper's kitchen; he should have thought the regulations of the poor-law commissioners would have prevented this. He then commented on what he called the shuffling way in which the medical witnesses gave their evidence, and said it was a pity that parties belonging to a profession so useful, and, when properly carried out, so honourable, should be led to bias their minds on a matter of such importance. He thanked goodness he was not brought up to the profession of a country surgeon. He would impress upon their consideration the fact that no traces of unfairness were to be discovered in the mouth of the child. There was no pretence either for saying that a spoon had been used; and how could a poison so strong and disagreeable to the taste be got down the throat of an infant so young without leaving some ill effect behind in the mouth of the child? He enlarged on the fact (acknowledged by Mr. Cossens) that all the appearances in the lungs, brain, &c., of the child might be accounted for by natural causes. A great deal had been said about the state of the clothes. Why, it was acknowledged that the children with the ringworm went to all parts of the house, and where would they more probably go than to see the last new baby? Besides, one of the articles that was said to be torn by the acid was the child's cap, so that at least they would acknowledge that it was not likely that the top of its head would be affected by what was poured into its throat. It was well known that children the most healthy had frequently died

suddenly of convulsions. Especially in this neighbourhood, where the heir-apparent of one of the proudest families in the country had died, was this fact known. And if this was the case—if a child, surrounded by all the luxuries and comforts which this life could afford, had baffled the most eminent of the medical profession in the kingdom in the attempt to discover the cause of its death—was it not probable that the son of an unfortunate pauper, possessed of none of these advantages, might die under similar circumstances? He was sure they would give the fullest consideration to the evidence which had been laid before them; and he was perfectly convinced that they could then arrive at no other conclusion than that it was insufficient to warrant them in finding this woman guilty of murder.

His Lordship then summed up the evidence. He thought, with the learned counsel, that it would be far better that a woman should perform the duties of visitor to the lying-in-room, and that it was highly improper to leave a bottle of deadly poison in a pauper's kitchen, especially where there was, as was the case in this instance, an idiot in the same room. He went through the whole of the evidence and commented on prominent parts of it. With reference to the evidence of the medical witnesses, his lordship remarked it was generally a matter of conjecture, of guess, which their scientific knowledge enabled them to make. It was not like the statement of an eyewitness, who might, for instance, see another person on a road. It was rather like seeing their footsteps, or the vestiges they might leave behind them, of which a person might form a very strong opinion that they were the footsteps of the certain other person. It was a matter of opinion and not a matter of fact. In this case, then, there were vestiges which might have been produced by other substances and not by the poison itself. He had heard that during the last twenty years the medical science had made rapid and wonderful advances. So he dare say it was said twenty years ago, and so it would undoubtedly be said twenty years hence; and probably the science would never arrive at perfection. It was very true that "man is fearfully and wonderfully made." The younger surgeon who had been called before them had spoken more confidently on the matter. They generally found it to be the case that the rising generation were more confident and thought they knew a great deal more than those who went before them; and undoubtedly they had the experience of those who preceded them. But he always found it to be the case that the more a man knew the less confident he was, and the more he found he had still to attain it. He then desired the jury to take the case into consideration, and return their verdict according to the evidence which had been brought before them.

The jury consulted for a few minutes, when they returned a verdict of *Not Guilty*.

The court then rose.

DEATH OF A LUNATIC FROM VIOLENT TREATMENT.—COMMITAL OF TWO KEEPERS.

THAMES POLICE-OFFICE.—On the 13th inst., two powerful men, named Samuel Garrett and James Downes, late keepers at the Grove-house Lunatic Asylum, Bow, Middlesex, were brought before Mr. Yardley, on remand, charged with having caused the death of a lunatic pauper named William Rank.

Mr. Clarkson, barrister, and Mr. Law, solicitor, prosecuted on behalf of the Commissioners of Lunacy. Garrett was defended by Mr. Pelham; and a gentleman from the office of Mr. Vann, a solicitor, appeared for Downes.

Mr. Clarkson, in stating the case for the prosecution, said the Commissioners of Lunacy, for whom he appeared, charged the prisoners with the manslaughter of a poor lunatic who was under their charge. They had no desire to excite any prejudice against the men at the bar,

but to put them fairly on their trial for the manslaughter of the deceased. He proposed, in addition to the evidence given on a former occasion, to call a convalescent patient, who saw the violence committed on the deceased, and who was in a fit state to give evidence. He should also produce other persons, whom the legal gentlemen engaged for the prisoners might call if they pleased. One of those persons had assisted in securing and beating the deceased, but he did not feel justified in charging him with the prisoners.

Mr. Pelham said he might see a necessity to ask some questions of the party mentioned.

Mr. Clarkson said he was in the court, and that the commissioners would keep back nothing.

Mr. Yardley would like to hear the opinion of the medical superintendent of the asylum as to whether the convalescent patient could be examined with safety.

Dr. Palmer, the gentleman appealed to, said the patient was quite free from excitement, and that he was to be discharged from the asylum to-morrow.

William Pride stated that he was an assistant to Mr. Byers, at the Grove-house Asylum, and had been so three months. He was engaged in No. 3 ward. The prisoners were employed as assistants in No. 1 ward. On Saturday, the 27th of March, the deceased Rank was a patient in No. 1 ward. On that day he heard a noise in No. 1 ward, which was next to the one where he was. He heard the prisoner Garrett ordering Rank to put his clothes on, and saw Rank standing on the floor in a tottering manner. Both prisoners were standing about three yards from him, and one of them had a strait jacket in his hand. They appeared to be frightened at Rank, and stood aloof from him. Witness seized Rank, whose back was towards the door, as he entered the ward. The blood was running down Rank's cheek in a stream. Garrett immediately placed a handkerchief round the deceased's neck and threw him on a bed. Garrett then pressed his knees on the lunatic's chest, and Downes at the same time commenced beating the deceased in a savage manner, and struck him ten or twelve blows with his clenched fists on the left side of his body. While Downes was beating Rank as hard as he could, Garrett stood up with one foot on the floor, and his other knee upon Rank. It appeared to witness that the whole weight of Garrett's body was upon Rank. While Downes was inflicting the blows with merciless severity, Garrett called out, "Give it to him; serve out the old devil." Witness repeatedly begged of them to desist; but they continued their ill-treatment, and struck him and kicked him again. Witness said, "Drop it." At that time Rank was getting nearly exhausted, and could not make any noise. The handkerchief was held tight round the man's neck by Garrett, and he could not breathe. The poor man foamed at the mouth, from which also the blood was flowing copiously. The prisoners then dragged Rank off the bed on to the floor, and put the strait jacket upon him. Rank never spoke after the sleeves of the jacket were tied or crossed behind him. Garrett was unable to fasten the tape of the strait jacket between the arm and the chest, and he took Rank by the shoulders and struck him four or five times with his knees in the right groin. Rank sighed and groaned heavily; he leaned forward, and the blood gushed from his mouth and nostrils. Garrett then gave orders for the patient to be taken down stairs and locked up in the cell.

In answer to questions by the magistrate, the witness said, that when Garrett forced his knee against the deceased, he said, "Keep in your belly, you old devil." He never saw Rank alive after he was locked up in his cell. He saw the body after the coroner's inquest. There were marks on the left side of his chest, where he was struck. They were black marks. He saw no violence on the part of Rank, nor any marks of violence on the persons of either of the prisoners.

In cross-examination by Mr. Pelham, Pride

said that Rank was struggling at the time he was lying on his back, but he did not see him kick or bite either of the prisoners. Rank was always a violent man, but he was not in the refractory ward.

Walter Mecklenburgh, a convalescent patient of Grove-house Asylum, who gave his evidence in a very precise and collected manner, stated that he slept in the ward No. 1, and the prisoner and the deceased also slept there. At daybreak on the 27th of March, Garrett called to him for assistance, and he got out of bed and found Rank attempting to strangle the keeper. One hand was grasping the keeper's throat, and with the other he was putting a strap over Garrett's head. Witness immediately seized him by his arms, pinioned him, and pulled him into the middle of the room. A struggle took place, and they both fell. They soon got up again, and Rank then recognised witness and said, "Oh, it is you; the last person I should have expected." Garrett then called for another keeper named Chumley, who slept in the next ward. Rank fell on his right side, with the arm of witness underneath. Chumley pulled the deceased back, threw him down, and struck him with great violence. Chumley got the deceased on the floor by kicking his legs from under him. Garrett had previously gone down stairs for a strait jacket, and when he returned he struck the deceased on the mouth and caused the blood to flow. Downes came into the ward at the same time and attempted to put the jacket on Rank, who resisted. Garrett called for a scarf or handkerchief, and one was thrown to him, which he made fast round the deceased's neck, and held him down with his knees on his body till the jacket was put over him. Rank became quite black in the face; his tongue protruded, and his eyes glared. It was such an appearance as a man would present who was being strangled. Rank struggled for a time, but the handkerchief round his neck was too much for him. He was overpowered and became quiet. The jacket was then made fast over him, and he was dragged to his bed. He was sure Rank became exhausted by the violent means used to subdue him. Garrett put his knees upon Rank, but not with any degree of violence. Downes struck the deceased several times, while he was down, about the body and side. Rank was striving to get away at the time. Garrett said to Downes, "Gently, that will do." He did not see Rank kick either of the prisoners. The deceased was fastened to his bed, and was not released until the other patients had breakfasted. The strait jacket was then taken off, and he became as violent as ever. He struck at Downes, but the blow did not take effect. Downes then struck him a violent blow on the side and knocked him down. Garrett went to the assistance of Downes, and held Rank down and pressed his head against the floor to prevent his rising. He did not see Pride offer any violence to the deceased.

The witness underwent a long cross-examination by Mr. Pelham, from which it appeared Chumley was in the ward at the commencement of the affray, and that Garrett would certainly have been strangled in his bed if the witness had not gone to his assistance.

Thomas Lynch, an assistant keeper, was sworn, and answered a few unimportant questions.

Mr. E. Palmer, the medical superintendent of Grove-house Asylum, stated that he was called to see the deceased on Saturday, the 27th of March. He was then confined. The strait waistcoat was upon him in a proper manner, and his arms in front. The patient was in a very excited state. Garrett had reported that Rank was violent, and accompanied him to the cell. The deceased began to threaten Garrett. He observed the man's left eye was contused, but saw no other marks of violence at that time. He gave orders for the patient to be kept in a state of seclusion, and prescribed medicine and a proper diet for him. In the evening he found the patient in bed, tranquil, but very sullen. He complained of pain all over. Witness asked

Garrett how the contusion on Rank's eye was produced? to which he replied, that Rank had attempted to strangle him; that, with the assistance of other keepers and Meeklenburgh, he had put a strait jacket upon him and confined him to the bed; and that when he went to get him up at breakfast time he was very violent, and he put him in confinement. Garrett also stated that the black eye was produced in the scuffle, but in what way he could not exactly say. On the same evening he again examined Rank, and found several contusions upon the left side, just over the ribs, and a contusion on the chest, which might have been produced by pressure. He passed his hand carefully over the man's ribs; they might have been fractured without his making the discovery then. The marks were those of recent bruises. He believed he did inquire of Garrett how the bruises were occasioned, and he answered by a general statement that the deceased was exceedingly violent. On the following morning the deceased complained of some pains and a giddiness in the head. The patient died on the 1st of April. On the morning after the occurrence in the ward there was considerable reaction, and he bled the patient. The symptoms gradually became worse till the evening of the 31st, when he discovered that an effusion of blood had taken place into the left pleura. From this period exhaustion progressed rapidly, and he died on the following day. The deceased had been under treatment for a disease of the heart while in the asylum, and he showed great mental excitement when the action of the heart was increased. After death, in consequence of the rumours that were communicated to him by other patients that the deceased had been cruelly treated, he wrote to the coroner, and an inquest was held on Saturday, the 3rd of April, and a verdict was returned, attributing death to a disease of the heart. In consequence of the evidence of Pride given on the inquest, he made a *post-mortem* examination of the body, and found contusions on the left side of the chest and in the left groin. The fifth rib on the left side was obliquely fractured at about three inches from its cartilage, the broken end of the anterior portion having perforated the pleura. The sixth and seventh ribs were transversely fractured about an inch further backwards than the fracture of the fifth rib. The eighth and ninth ribs were also transversely fractured, about an inch still further backwards. The broken ends of the sixth, seventh, eighth, and ninth ribs were in apposition, and the surrounding textures not torn. The witness, after describing the appearances at great length, said death was caused from effusion into the chest resulting from inflammation of the pleura, induced by the perforation of the fractured end of the fifth rib. He thought the ribs might have been fractured by pressure or severe blows, or by pressure of the knee. He afterwards examined the head and found nothing to alter his opinion as to the cause of death.

After a long conversation between the learned counsel and Mr. Pelham,

Mr. Yardley said he should commit the prisoners for trial for manslaughter.

Mr. Pelham made an energetic appeal to the bench in applying to the magistrate to accept of bail.

Mr. Yardley said he could not think of taking bail in a case of this serious nature, and committed the prisoners to Newgate for trial.

The deceased was fifty-eight years of age.

THE LATE RICHARD CASSON, Esq.,
SURGEON, &c.

On Friday, April 2nd, died, at his house in Gracechurch-street, London, Richard Casson, Esq., Surgeon. He had been in practice for many years at Hull, in Yorkshire, where he was highly respected for his sound professional qualifications, and for his sterling worth and honourable character.

In conjunction with the late excellent and worthy Dr. Alderson, he established the East

Riding Lunatic Asylum, which is now under the superintendence of his son, Mr. F. W. Casson surgeon. In this institution he manifested all the higher attributes of his character by devoting his clear and lucid intellect to ameliorate the physical and moral condition of his patients. And so kind and considerate he was with them, that his daily visits diffused a gleam of pleasure even to the most melancholic.

Facts might be cited to prove that his love for his profession was sincere, and his ardour in obtaining a thorough knowledge of it, zealous and untiring. This was not only the case in reference to his general practice, but was shown in his benevolent efforts to mitigate the real or imaginary sufferings of the insane, in which he was aided by his benevolent colleague, who thus jointly introduced every rational treatment, and were, therefore, in advance of their age. (a) In his manners he was mild and firm; and possessed great self-dependence, with extraordinary presence of mind in any sudden emergency. And such was his urbanity and gentlemanly bearing, that when consulted by his juniors, or by men of his own standing, he never dogmatized, or suffered any expression of his opinion to lessen their own self-esteem. His opinions were put in such a way that it would seem as if the intellect of his professional quorist had excoagulated them.

His diagnoses were always sound, because he did not treat for symptoms, but for their causes. And, although in an extensive practice for many years, he always found time to keep up his knowledge of every discovery in medicine, surgery, pathology, &c. His sound and discriminating judgment showed great facility in distinguishing the *obvious* and the *true*, from what was merely speculative or hypothetical.

Indisposition obliged him, two or three years since, to leave the place of his nativity, and the field of his extensive usefulness. And, as London seemed to agree with him better, he became a partner of Mr. English (one of his talented pupils), and, had his life been spared, he would in all probability have obtained an extensive practice in the metropolis. He died a comparatively young man, not quite fifty-six years old, from an exhausted frame (b), but with a mind full of knowledge, and a heart full of kindness; respected by his contemporaries, esteemed by numerous friends, and deeply lamented by his intelligent widow and numerous family.

The writer of this brief notice will long cherish his memory, not only for his worth as a man, and for his professional ability, but for his moral courage. Among other evidence of the latter might be cited the fact that he advocated phrenology when it was *tabooed* by the profession, and by the public it was regarded as a species of "black art." But he was one of its earliest advocates in this country, acknowledging, on all occasions, his conviction of its importance in the treatment of the insane; and about the year 1825 or 1826 he formed, with some few medical men, "The Hull Society for Phrenological Inquiry," a society not satisfied with mere assertions; and the late illustrious Dr. Spurzheim often, when speaking of it to the writer, called it a model institution worthy of imitation.

The *Hull Advertiser* of April 9, after speaking of his demise, concludes the article with the following just and honourable tribute:—"In all relations of private life he was amiable, upright, and benevolent. His attachment to liberal principles was as steady as his views were sound and comprehensive. He will long be lamented by a wide circle of friends, and by none more sincerely than the poor, whose friend he was throughout the whole of his professional life." Brighton, April 18. J. L. L.

(a) The writer of this article alludes to a period of more than twenty years past, when he himself in practice in Hull, without detracting anything from the merits of Dr. Connolly, &c.

(b) Not having heard anything of a *post-mortem* examination, I am not certain what caused his death. He used to acknowledge that he was suffering from chronic bronchitis.

GOSSIP OF THE WEEK.

APOTHECARIES' HALL.—Gentlemen admitted members, April 8:—Frederick Mason, Charles Astley Walters, Charles John Gibb, Charles William Izod, Thomas Sympton, Henry John Waterland, John Lloyd, John Jones Parrish, Samuel Osborne Habershon, Howard Frederick Johnson, John Packer, Richard Branwell, John Willan, Joseph Marshall, Simon Caldcleugh, and Samuel Clewin Griffith. April 15:—Frederick Freeman Allen, William Palmer, William George Harvey, William Mott, William Ellis Hambley, Abraham Jubb, junior, William Price, Edward Haycock, and William Alexander Bryden.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma of this college were admitted members on the 16th instant—viz.: Messrs. Peter Augustus La Farque, Asylum-road, Old Kent-road; Walter Yonge, St. Ives, Cornwall; Frederick Moore, Shelsley, Beauchamp, Worcestershire; Samuel Wilks, Camberwell; Hugh Robert Rump, Wells, Norfolk; Thomas Webb, Cheddle, Staffordshire; John Edward Ellerton, Aberford (near Leeds); Edward Adams, Great Barton, Suffolk; William Daniel Michell, Truro, Cornwall; David Hughes, Plas Trewydd, Llandepla, Ruthin; and Charles Mundell, King-street, Snow-hill. At the same meeting of the Court Mr. Henry Piers passed his examination for naval surgeon; this gentleman's diploma from the same college is dated December 11, 1840.—April 21st: H. B. Gibbon, J. S. Pearce, J. E. Gannon, J. T. Campion, A. Ferguson, W. P. Shipton, W. H. Sproston, J. V. Hughes, W. M. Fairbrother, J. L. Cotter, J. Harwood, R. D. Harris, and G. Fry. The Jackson Prize has been given to Messrs. Calaway, jun., and Mr. Hudine.

MIDDLESEX HOSPITAL.—There has been another meeting during the last week of the Governors of this hospital, the affairs of which are as mismanaged as most others of our London Infirmarys, and are even in worse confusion. Some complaints against the medical officers were abandoned; and the hospital is left in no improved position by the termination of the squabbles.

MORTALITY TABLE.

For the Week ending Saturday, April 17, 1847.

Causes of Death.	Total.	Average of 5 Winters.
ALL CAUSES.....	981	914

OF

LECTURES ON SURGERY,

BY

SAMUEL COOPER, Esq., F.R.S.,

Professor of Surgery to University College, London
Consulting Surgeon to London University Hospital, &c.

LECTURE III.

At the conclusion of my last lecture I noticed the circumstance that one disease may be the exciting cause of another. To afford you some further illustrations, I may mention that fractures, wounds, or dislocations, or other mechanical injuries, may cause abscess, necrosis, tetanus, and other forms of disease. Aneurism is often the secondary result of atheromatous or osseous deposits between the coats of the arteries; and these osseous deposits, frequently occurring in old age, so diminish the calibre of the arteries of the extremities as to prevent a sufficient supply of blood to the limbs, and produce chronic mortification or dry gangrene. Disease of the bladder is by no means an unfrequent result of injuries to the spine. The bladder becomes paralysed; the urine accumulates, or is imperfectly evacuated, is rendered ammoniacal, and causes irritation and inflammation of the coats of that organ, often attended with softening. Again, disease of the bladder is frequently the result of enlargement of the prostate gland. The walls of that organ become thickened or sacculated, so that pouches are formed between the fibres of the detrusor urine. Thickening of the bladder, the formation of sacculi, ulceration of that organ, and fistule in the penineum are by no means unfrequent results of strictures of the urethra.

Under specific exciting causes, we include the animal morbid poisons which give rise to contagion. The full consideration of this interesting class of causes would lead me into a wide field of discussion of rather a medical than a surgical character. Some of them, such as the venereal and hydrophobic poisons, will come under our notice in their proper place. Specific causes are divided into direct, when communicated immediately from a diseased to a healthy person; indirect, when conveyed through the medium of clothing or bedding. Some infectious diseases require contact, others may be transmitted in the indirect manner.

It is necessary for me to say a few words to you on the meaning of a term in daily and hourly use among medical practitioners—the word *symptom*. You cannot possess too precise an idea of what is meant by this term. The word *symptom* is used to designate any perceptible change in an organ or function which is really connected with the disease under which the patient is labouring. It is important to bear in mind that any alteration

which does not depend on the disease is merely an accidental circumstance, and not a symptom.

A proper distinction has been drawn between *symptoms* and *signs* of disease. Symptoms are manifest to the senses, while signs are deductions drawn from a careful consideration of the causes, progress, complications, and the results of treatment. Symptoms have been frequently divided by pathologists into those which are common to many diseases, such as pain and difficulty of motion, which are common to fractures, dislocations, contusions, rheumatism, and other diseases; and into *proper* or *essential*, which invariably accompany particular lesions, as the grating noise or crepitus in fractures, the change in length or shape of a limb in dislocations. Pathognomonic signs are those peculiar to some one disease, which therefore show themselves in no other, and afford a certain indication that the particular disease is present to which they belong. As an example of a pathognomonic sign, I may bring forward the collision of the sound with a stone or other extraneous body in the bladder.

It is by a careful inquiry into the symptoms and signs of diseases that we are enabled to distinguish them. The term *diagnosis* is applied to the art of distinguishing diseases. Of all things connected with the removal of disease, the diagnosis may be said to be among the most important. If you have accurately diagnosed a disease, you will be enabled to predict its future progress and termination; to which predictions the term *prognosis* is applied. You can only acquire proficiency in this important department of pathology by a most careful examination of all the circumstances connected with the disease, and accurate inquiry into its causes and symptoms; which you must compare with the causes and symptoms of other diseases which approach it in character. As diagnosis is the most important, so it is the most difficult, part of our profession: by it we learn the nature of each form of disease, and what should be aimed at in treatment, or the curative indications on which our treatment must be founded. It might be expected that, in so difficult a branch of inquiry, mistakes frequently occur, attended in some cases by the most deplorable consequences to the health or even the life of the patient, and the injury or ruin of the reputation of the practitioner. One mistake frequently gives rise to another, so that, if you commit an error in diagnosis, the probability is that your prognosis and treatment will be equally incorrect.

Most of these mistakes may be avoided—first, by careful attention to your studies in this institution and in the hospital; and, afterwards when in practice, by a sedulous attention to the symptoms of disease. All may err in diagnosis, however competent they may be to the practice of their profession; because obscure cases frequently present themselves in which the symptoms are of so indefinite a character as to lead the most experienced into error.

How frequently do we see mistakes made in the diagnosis of pregnancy and affections of the

uterus; how often are limbs amputated which might have been saved; how frequently are hydroceles mistaken for sarcoceles; hernia confounded with glandular enlargements; dislocations with fractures, and contusions of the hip with fractures of neck of the femur!

Cases have not unfrequently occurred where patients have been cut for the stone, and none found; amputations of the penis for supposed carcinoma, where only the prepuce was affected!

Beclard relates a case where a man who had a fistulous ulcer in the cheek was attended by a surgeon who, having dressed it for three months, was surprised to find the dressings tinged with a fine green colour when taken off. On probing the fistula, Beclard detected a foreign body in it, which turned out to be the copper head of a walking-stick. It was removed, and the wound healed.

I have now said sufficient to induce you to turn your most careful attention to the diagnosis of disease; but I may add another argument, that, although the public will frequently tolerate the most fatal mistakes of an impostor or quack, they will never shield the legal practitioner from the disgrace that attaches to an important error in diagnosis.

Prognosis is the judgment or opinion given on the changes which may occur in the progress of a disease, the benefits to be expected from treatment, and the final termination of the case. The delivery of the prognosis of a case is, therefore, of great importance to the reputation of the practitioner, and becoming caution must be used in giving it.

The prognosis is in all cases founded on a proper consideration of the causes, seat, intensity, and nature of the disease; on the sex, age, and profession of the patient; his vital powers; the complications, if any, of his disease; the effects of previous treatment, and on the degree or severity of any operation that may be requisite for the removal of the disease.

It is necessary to be generally reserved on the subject of diagnosis, and not to give too confident an opinion where any degree of uncertainty exists, unless with considerable qualification. It is a frequent error with young practitioners to speak with too great confidence on the prognosis of a case; further experience shows them the uncertainty of the progress of disease, and teaches them to avoid too great confidence. The foretelling the event of a disease correctly raises a surgeon in public estimation; but it must be remembered, on the other hand, that, if his opinion be contradicted by the result, he loses more reputation than he would have gained had his prediction corresponded with the result.

Neither must we be too confident in foretelling the death of patients who are apparently verging on death: for patients sometimes recover under the most apparently hopeless circumstances; while others die from the most trivial injuries. In the Museum at Leyden a large bombshell is preserved which entered the perineum of a soldier, and escaped through the walls of the abdomen, and yet this man re-

covered. A French soldier was struck with a grapeshot, at the battle of Talavera, which fractured the pubis, entered the bladder, and made its exit through the sacrum. He soon recovered from these injuries, but a stone in the bladder was afterwards discovered, for the removal of which lithotomy was performed. The calculi extracted by this operation had fragments of the pubis for their nuclei.

Another man, in Paris, allowed the blade of a sword, about twenty inches in length, to slip down his throat; an abscess formed in the groin, from which the sword blade was extracted, and the man recovered. These are a few out of the many instances which might be brought forward of men recovering under the most unexpected circumstances.

Again, trivial injuries may be followed by most fatal consequences. Erysipelas is by no means a rare consequence of operations, even of the most trivial character. I have met with several instances where severe and fatal erysipelas of the head and face has resulted from some slight operation. A lady consulted me some years since for a little tumour on the nose, not larger than a pea. I advised its removal; which was afterwards done by Sir A. Cooper. Within a week after this operation she died of erysipelas of the head and face. Death has resulted from the removal of an incurved toenail, from dividing the prepuce, from the insertion of a seton, and even from the passing of a bougie or catheter. Disease may terminate in several ways:—1st, in a perfect cure, or complete restoration of health; 2nd, in an imperfect cure, where the disease is much mitigated, although not entirely removed—as in fractures, when united with much shortening or deformity of the limb, or in the operation for cataract, which always leaves the sight more or less defective; 3rd, in a cure, with the loss of certain organs, as in amputations, extirpation of the eye, the testicle, breast, or other parts; 4th, acute diseases may terminate in becoming chronic, or by changing into others—retention of urine, for example, sometimes terminates in a urinary abscess, followed by fistula in perineo, and artificial anus may be a result of sphacelated hergia.

I must now draw your attention, gentlemen, to the classification of those diseases which belong to the department of surgery, and lay before you the plan of the present course of lectures. That the adoption of some arrangement facilitates the labour of instruction, both to the professor and the student, cannot be doubted: for the diseases reputed surgical include a large number of accidental injuries, as well as diseases spontaneously arising in the human body. The number being so great, and the nature of these accidents and diseases being so diverse, confusion would occur were we not to adopt some form of arrangement.

The classification of diseases is attended with extreme difficulty, so that, although nosology has occupied some of the greatest minds that have adorned our profession, none of their endeavours have been attended with perfect success. The difficulty becomes much greater when we endeavour to draw a line of demarcation between medical and surgical diseases, as I have already explained in my introductory lecture, because they do not admit of a precise separation, and the science on which the comprehension and treatment of them is founded is absolutely one and indivisible.

A complete nosological arrangement or nomenclature and classification for diseases should properly include the whole of them; but when an attempt is made to divide such an arrangement into two portions, physic and surgery, the difficulty is materially increased. Under such circumstances the classification would be mutilated and unnatural.

Classifications in natural history, in botany, zoology, and mineralogy are of the highest importance, and made with greater facility, because the objects which are classified in these sciences present much more definite and certain characters than those usually presented by disease.

In disease, the peculiar features or differences are far more vague and uncertain in their nature, and at the same time of a deceptive character. The distinguishing marks of plants, animals, and minerals are permanent; those of diseases transient and variable. The divisions of animals into those which have red blood, and those whose vascular system contains a colourless limpid fluid into warm and cold blooded animals, or vertebrate and invertebrate, is founded on anatomical and physiological characteristics which are immutable in their nature. No system of arrangement in natural history which is based on definite structure, function, or habits of animals and plants, can ever fail to be permanent. The division of animals into herbivorous and carnivorous, and the subdivision of the former into those that ruminate or chew the cud, will stand as long as Nature herself exists. The classifications of the botanists are founded on similar rational principles. The presence number, or absence of the cotyledons, in the seed the mutual positions and number of the parts of the flower, constitute permanent distinctive marks on which a natural arrangement can be based. But in the formation of a nosology, or system of arrangement and nomenclature, of disease you will observe that these are not always so readily distinguished from each other that their essential differences can be ascertained with any degree of certainty. No abrupt line can be drawn between a healthy and diseased condition of the body, the one melting, as it were, into the other; and this approximation of different diseases, by insensible degrees, is one of the chief obstacles to nosological arrangements. It must be borne in mind, that animals and plants are distinct beings, while diseases are purely modifications of the same textures, organs, or functions. However imperfect nosological classification may ever be, you must not despise the attempts which have been made to arrange diseases, and you will find much that is valuable in systematic nosological works.

The ordinary mistake into which nosological writers have hitherto fallen is that of taking what are really symptoms for diseases. Thus, paralysis, dropsy, convulsions, dyspepsia, many varieties of ulcer, as well as numerous other affections, are merely symptoms of other and more serious lesions. You will discover, on looking over any of our nosologies, those of Cullen or Sauvages, for example, that a very considerable proportion of the affections there set down as diseases are truly symptoms or consequences of other diseases.

We cannot then be astonished, after what I have said, that the systems of nosology propounded by successive authors have presented imperfections which have caused them successively to fall into oblivion. In investigating the nature of the elementary tissues, Bichat, the greatest physiologist of France, conferred an immense benefit on science; and, although the subsequent progress of microscopical investigation has thrown some portions of his immortal work into the shade, we cannot but feel grateful for what he accomplished. Although the organs and textures of the human body are numerous, the tissues which enter into their formation are few. They were divided by Bichat into cellular, osseous, mucous, serous, glandular, muscular, dermoid; but still more recent investigations have reduced these to a much smaller number, by showing that a considerable proportion of them are truly made up of modifications of cellular tissue. We might, taking the tissues as the basis of our classification, describe separately the diseases or changes to which each of these tissues are liable, and thus construct an anatomical system of classification, were we always certain of the tissue in which the disease commences; but we are often uncertain on this point, and we very well know that diseases in their progress often involve several of these tissues. Phlegmonous inflammation and abscess are not confined to the cellular membrane, but commonly implicate other textures, and may, perhaps, commence in them. An arrangement of surgical diseases

based on the classification of the tissues must, therefore, be necessarily imperfect, as it obliges us to state in what particular tissue a disease has commenced, or in its course has involved. Another great disadvantage attendant on such a system of classification is, that it would bring together a number of diseases between the characters of which no analogy can be discovered.

Whatever arrangement may be adopted must bring together the different diseases of the same organ or part of the body; and, therefore, instead of a classification of diseases founded on the particular tissue affected, or supposed to be affected, I shall prefer the classification which gives a separate view of the diseases of each organ, or system of organs, which are concerned in each particular function.

In your attendance on the practice of our hospital you will discover that the greater portion of those diseases that come under the care of the surgeon are attended with inflammation, suppuration, ulceration, erysipelas, wounds, fractures, hemorrhages, or other mechanical or chemical injuries of the body.

It is the usual practice of writers and lecturers on surgery, to commence with inflammation and its consequences. The utility of this plan is manifest, because inflammation is either a cause, a concomitant, or a consequence of most surgical affections; and I shall, therefore, follow this arrangement in the present course of lectures.

I shall first bring under your notice, inflammation with its common effects and occasional consequences, suppuration, ulceration, and mortification. Wounds, hemorrhage, and some other general matters, will follow in succession, as constituting the rudimental surgical subjects. These will be followed by the remaining mechanical injuries; diseases of the bones, arteries, veins, and other organs; then tumours and specific diseases.

The first part of the lectures will, therefore, contain general surgical subjects, or those injuries and diseases which are common to the whole or several parts of the body, but not confined to one particular part.

In the second part I shall place before you particular surgical matters, or the injuries and diseases of individual organs and regions.

A COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the Theatre of Queen's College, Birmingham.

By SAMUEL WRIGHT, M.D.

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Cuvierian Natural History Societies of Edinburgh, &c.

Influenza of 1846; circumstances of its occurrence; probable causes of it; comments; what is influenza; transmission of it from one county to another; difference of atmospheric states the cause of its epidemic spread; other causes of its isolated occurrence; comments thereon; is influenza a communicable disease; proofs against it from the author's experience; nervous debility of influenza attempted to be localized; pneumogastric nerves assumed to be chiefly at fault; objections to this theory; the nervous depression general, and particular manifestations arising out of this; characteristics of the influenza of 1846, and treatment of it.

GENTLEMEN,—Most of you will remember my saying at the hospital, one morning in the autumn of last year, that, if the weather were suddenly to become cold, the typhoid fever would be stopped, and we should be likely to have something resembling influenza in its stead. Strangely enough, within a week, as I afterwards remarked to you, this very atmospheric change occurred, and catarrh took the place of the low fever.

I do not mention this as any proof of my aptness at prediction: few men are less inclined

to it, or less skilled in it, than I am, for I am rather habituated to specific than to speculative data; but I remind you of the fact, first, because the coincidence was somewhat curious; and secondly, because it serves as an introduction to the subject-matter of this discourse.

The ailment that was successive of the typhoid fever of last year had all the characteristics, special and general, as you know, of influenza. I believe it to have been this, though in a milder form than I have aforetime met with it. In pronouncing it influenza, then, you must not suppose that I impute its advent to the cold. The history of this disease tells us that variations of temperature have little or no influence over its rise, progress, or termination. The influenza of 1762, one of the severest ever known, occurred during the prevalence of very warm weather; that of 1767, on the contrary, also very severe, happened when the weather was remarkable for its coldness; that of 1833 was when the weather was particularly mild. The seasons, again, have no control over it: in spring and in autumn, in summer and in winter, it has prevailed epidemically, and been equally fatal. I do not say, therefore, that the cold produced the influenza I speak of, but I cannot help thinking it contributed somewhat thereto. At least I think it was the cause of the irritation in, and discharge from, the air-passages. One of the most common causes of ordinary catarrh is a chilly state of the atmosphere suddenly supervening upon a mild or a fervid one. This was what occurred last year at the period I refer to, and nasal and tracheo-bronchial defluxion was the immediate consequence. The catarrh came, to all appearance, as a result of the sudden accession of cold weather: it attacked people indiscriminately; the healthy and robust suffered from catarrhal symptoms merely; those who were debilitated by previous fever, who were recovering from it, or were still slightly under its influence, exhibited all the features of influenza when catarrhal symptoms became added to those of extreme nervous debility. It was a suspicion that such would be the case that led me to surmise the advent of something similar to influenza, should a sudden chill come upon the moist warm atmosphere. At the time I spoke of this, lesion of innervation was the prevailing pathological characteristic in most of the acute ailments then existing: to this condition of the nervous system, let catarrh be superadded, and then, what have we but influenza? This, in fact, is nothing more than catarrh, with great nervous depression. At least this is the pathological light in which I view it. You may ask me, do I not regard influenza as a specific form of complaint? I am not prepared to say that there is any evidence of any radical pathological state belonging to it, further than that which is manifested in the two leading features I have adverted to. It generally prevails epidemically, sweeps over vast tracts of country at once, and, like cholera, has usually extended from the south, northwards, and from the east, westwards. But this proves nothing more than that the disease may, and probably does, as an epidemic, arise from a particular state or states of the atmosphere. I say *states*, because it is not improbable that several of these may give rise to epidemic visitations of influenza, at one time or another, yet each preserving the distinctive peculiarities of the ailment. An unknown and unaccountable atmospheric condition will give rise to typhus; so will living in a low damp situation; so will exposure to noxious effluvia; so will eating putrescent food. Yet the typhus is the same disease, from whichever of these several causes it may have sprung. So with influenza. If at one time it seems to arise from some *temperies aris occulta*, it is not the less influenza at another time, if the probability of its origin be more apparent. If, owing to some atmospheric singularity, there be a general tendency to vital depression amongst living beings, and to this succeeds defluxion from the air-passages, what ought the disease to be called but influenza, in the absence of pathological

proofs of its wanting any other denomination?

Some will have it that influenza only appears epidemically, attacking multitudes of people at once; and giving plain proofs of whence it has come and whither it is tending. That this has often happened there is no doubt: the re-visitation of the malady in London, in 1833, after an absence of thirty years, is a good example; but my own experience inclines me to think that it often enough appears in isolated cases, called, variously, bronchitis, cold, fever, &c., but which would unhesitatingly be regarded as influenza if any one of such cases were found associated with many others like it. I have often heard it remarked, of as plain a specimen of the ailment in question as I ever saw, "how uncommonly like influenza this is." "If influenza were prevalent just now, I should decidedly say this was a case of it." Of cholera the same was said after it had ceased to attack numbers of people at once. It was regarded as real cholera, when hundreds were its victims daily; it was only very much like itself when these victims were "few and far between." Yet it was the same cholera, in type and in the severity thereof. There is nothing, however, like experience, to dissipate prejudices such as these, and awaken men's minds to the truth of passing events. It was not until the devastation by the influenza of 1837, when three hundred and sixty-four persons died of it in London, between the middle of January and the middle of March, that the nosological term was admitted into the bills of mortality of the metropolis. Now, as you are aware, it figures conspicuously as one of the ills that flesh is heir to.

Whilst some believe that influenza can only appear as an epidemic, others believe that the disease can only be worthy of its name when it comes like a very pestilence, seizing and making victims by wholesale, and giving undeniable proofs of being both infectious and contagious. It is probable that, in the cases given in proof, the mistake has been made between *communication* and *common cause*. A number of people having been attacked simultaneously, or successively, has led to the belief that each has had something to do with infecting every other; whilst the fact has likely been, that all have suffered exposure to the same general morbid agent, and that those most susceptible of its influence have shown their susceptibility in being partakers of the common malady. I have never, myself, met with the smallest proof of influenza being either infectious or contagious. It made its appearance in the town of Nottingham about twelve months after the subsidence of the cholera that I spoke of in a previous lecture. It occurred in a very severe form, and was the occasion of a greater mortality, though less suddenly, than its dreadful predecessor. I had many painful opportunities of witnessing its ravages, but without once detecting its direct or indirect communicability. The earnest advocates of its contagious nature, that is, of the capability of extending the disease from one individual to another, through contact with the mucous defluxion, have endeavoured to liken it to the distemper in dogs, or to the glanders in horses. I can only say for myself, that I have never seen the least approach to such pathological similitude. I believe a famous author, Weber, once fancied that influenza was occasioned solely by the atmosphere being in a state of negative electricity; but I am not aware that his remedial suggestion of nonconducting garments had any prophylactic or curative influence.

It has, further, been attempted to *localize* the nervous debility which is one of the pathognomonic features of influenza; and the pneumogastria have been fixed upon as best calculated to bear the burden of the speculation. This had seemingly arisen from the fact that the function of respiration is often feeble, or hurried, or irregular, as the case may be, in influenza. Examples of this kind certainly do often occur in the disease in question, but they are quite as often absent, and I can therefore see no pathog-

nomonic value whatever in the symptom. The function of alimentation is often imperfect in influenza, as well as certain other functions with which the great sympathetic has something to do, but we must not thence say that this nerve in a morbid state is the chief source of the mischief. My own experience inclines me to think that in the cases (by no means constant) in which there is irregular respiration in influenza, this is due to an irregular action of the heart consequent upon the general nervous debility. Nothing is more common than difficulty of breathing from mere weakness; we see it every day, and can easily account for it, in the absence of organic lesion, without having to refer to any occult defect of this nerve or the other ministering to the respiratory or circulatory functions. Influenza has a general and a particular character—nervous depression and catarrh; this is all that we know of it from observation during life, or from examination after death. True, a variety of *post-mortem* appearances are sometimes found, such as congestion of the bronchial membrane, pus or mucus in the bronchi, spumous with congestion of the lungs, congestion of the brain, &c.; but it is easy enough to see that all these are *effects*; that they are secondary pathological items, and not leading ones. Again, there have been no morbid appearances whatever! I do not believe that the ailment is anything more than its usual manifestations indicate it to be; I think that many of what have been supposed to be leading pathognomonic features are only sequences of the nervous depression; and I disbelieve utterly in the communicability, directly or indirectly, of the disease.

To consider, now, the influenza that appeared in this town towards the close of last year. As I told you, it came immediately upon the accession of the cold weather: the typhoid fever subsided almost as suddenly: I did not see half a dozen cases of fever, and those were very mild, after the sudden change in the atmospheric temperature. Like this fever, and like the bowel complaint that preceded it, the influenza seemed to have no choice of locality, but to visit promiscuously the houses of the rich and the poor; those situated in airy, elevated spots, and those in low ill-ventilated ones. It has often been remarked of epidemic influenza, that it has a tendency rather to attack the strong and robust of middle age, than elderly people or children. It was not so with the one I speak of: age, sex, or temperament, seemed little to direct or regulate it. It exhibited, however, two varieties, according to the previous health of the individuals attacked. Those who were tolerably well at the period of seizure, suffered simply from catarrh; those who had been debilitated by fever, or other causes, furnished all the ordinary evidences of influenza.

The catarrh came, as it generally does, with a slight antecedent fever, listlessness, drowsiness, and oppressive headache. The pulse rose in force and frequency; the tongue became covered with a pale fur; there was thirst, loss of appetite, and a diminution or depravity of the secretions. Shortly, that is, in from a few hours to a day or upwards, a slight hoarseness and cough succeeded; the latter increased, and the former gave place to a copious thin mucous expectoration. In other cases there was no cough or hoarseness, but excessive pain across the forehead, chiefly in the situation of the frontal sinuses; congestion and itching or soreness of the Schneiderian membrane, lasting several hours, and then followed by frequent sneezing; and a profuse discharge from the nostrils; generally the eyes became injected and swam with tears.

In the milder of these cases, little treatment was necessary. Their duration varied from a few days to a week, and they often recovered without the aid of medicine. In some, the morbid symptoms subsided, as they had begun, spontaneously; in others, a critical sweat appeared to prove curative; and in others, diarrhoea seemed to be so.

The severer cases required more management; and that was most serviceable which was prompt and decisive. A brisk calomel purge at the commencement did more and better remedial execution than anything else. In many instances it rendered further treatment unnecessary. Several cases I saw, of considerable severity, and threatening to be of some duration, completely arrested by the operation of a single dose of calomel. Copious bilious stools were first produced, and upon their evacuation came an almost immediate cessation of the more unpleasant symptoms. The pulse fell to its proper standard, or a little below it; the headache and oppression vanished; the thirst and feverishness subsided quickly; the secretions became restored; and the skin especially acquired a softness and a moisture. Beyond a further aperient, it was seldom, in these cases, that anything was needed after the action of the calomel. In many instances, however, it was not advisable to give a mercurial purge to the extent I have stated, for fear of inducing too great a degree of debility. A moderate dose of grey powder, followed by a mild aperient (and these repeated if necessary), was then of good service. Here, though, it was seldom that the attack was suddenly cut short, as in the preceding cases. The secretions were slowly, not quickly, restored; and they required to be further aided by saline diaphoretics. This form of treatment generally sufficed to mitigate the more troublesome symptoms in the course of a few days, and by the end of a week the patients were usually convalescent. When the return to health was tardy, it was hastened by the administration of vegetable butters, with an alkali. When expectorants were indicated, they were best given in conjunction with the tonic; but it seldom happened that the cough and expectoration were not relieved directly with the improvement of the digestive organs.

The influenza, as I have said, was manifested when catarrhal symptoms supervened upon those of general debility. Very few were the exceptions to this rule. I met with two or three cases in which it was not very clear what amount of general ailment had preceded the cough and coryza; but the sources of information were not sufficiently intelligent to justify me in forming an opinion contrary to what I have stated to have been the usual rule.

The leading feature and source of complaint in this form of the catarrhal epidemic was nervous prostration. It was variously shown. Some were perpetually shedding tears, and saying they could not help it; others sighed and groaned, and gave themselves up to despair; others by listlessness, and could scarcely be induced to speak a word; others complained of weakness of their limbs, and aching of them, a sense of sinking at the epigastrium, faintness, &c. The pulse, as a rule, was very quick and feeble, and in some rare instances, irregularly intermittent. The respiration was also very often irregular, sometimes hurried, at other times slow, and again laboured, with interruption, constituting a troublesome form of dyspnoea. As I have said, this state of the respiratory function, in the majority of cases, appeared to me to be secondary of an altered action of the heart; and this, again, of general nervous debility. The exceptions were, when there was an obvious condition of the respiratory apparatus to account for the altered action of it. Turgescence of the laryngeal membrane, or of the bronchial membrane, with consequent constriction of aperture and canal, was not an unfrequent cause of difficult or interrupted respiration; profuse accumulation of mucus in the bronchi was another; so was serous extravasation into the air-cells of the lungs; so was pulmonary congestion. Correspondently with these states were various physical signs indicating them, with which you are sufficiently familiar not to render it necessary for me to give them in detail.

In the influenza the fever and oppressive headache were less remarkable than in the simple catarrh. Frequently, indeed, there were no feverish symptoms at all, or, at most, only

slightly, and in an evening. The tongue was very pale and trembling; there was little thirst; usually the skin was moist, and often abundantly bedewed with perspiration; the defluxion, nasal or tracheo-bronchial, was excessive, and generally very thin. The bowels were seldom costive, but the biliary secretion was insufficient; the kidneys acted sparingly, and the urine was either loaded with lithates or turbid and milky-looking with mucus; rarely did it contain albumen.

These cases, for the most part, were successfully treated on the sustaining plan. There was no fever, as I have told you, worth considering; the two great troubles to be met were the debility on the one hand, and the defluxion on the other. Of these, the former was by far the most important; the patients might not only sink through it, but its persistence might lead to a secondary train of evils fatal in their consequence. The discharge, whether nasal or bronchial, was a sort of pathological effort at cure, or at any rate at relief: by the former the brain was saved congestion; by the latter the lungs. Had either been stopped the probability is that its corresponding organ would have suffered immediately, and that sympathetic fever would have soon followed. Leaving the defluxion alone, then, as a sort of sanatory outlet, our attention was directed, as you know, to sustaining and invigorating the nervous system, and improving the secretions. The first object was chiefly answered by the exhibition of vegetable tonics, such as gentian, calumba, or casparia, with ammonia. When the urine was scanty, and lithates abundant in it, nitric ether and bicarbonate of potass were useful adjuncts. In the majority of cases, this form of treatment was singularly successful: the debility gradually disappeared, and as gradually were the appetite and secretions restored. In a few cases in which the ammonia could not be borne, a stimulating bitter tincture advantageously supplied its place. Some of you remember how soon, and how satisfactorily, even severe forms of dyspnoea, with loud mucous rale all over the chest, subsided under these measures. Occasionally, however, the pectoral symptoms were sufficiently urgent to call for more direct treatment. When the bronchi were loaded with mucus, difficult of expectoration from its viscosity and thickness, a preparatory emetic was of great efficacy. The addition of ipecacuanha wine, or of squills (according to circumstances) often increased the value of the tonic mixture. When the bronchial accumulation was very great, or there were evidences of pulmonary congestion, blistering or counter-irritation of the chest did great service. I never advised, or saw tried, local bleeding in these cases, nor can I think it could have proved other than mischievous. Mercury was indifferently borne in this influenza. More than once, I saw even a small dose of calomel produce alarming symptoms, even though it had acted not energetically upon the bowels. Blue pill, with soap and opium; or grey powder, either alone or with Dover's powder, answered best when the torpidity of the liver indicated special treatment. But, as I have said, and as yourselves saw, most of the minor symptoms subsided as the nervous vigour became restored; to improve this, was the great indication; what was then left unremedied was easily afterwards corrected.

DUMAS ON ORGANIC CHEMISTRY. No. XVIII.

ON THE URINE.
(Continued from page 130.)

GUANO.—Upon the islands and rocks bordering on the coast of South America, between the 13° and 21° of latitude, we meet with very abundant deposits of an animal matter formed of the excrements of innumerable birds which inhabit these solitary regions. This matter is known under the name of *guano*, and is found in strata frequently upwards of twenty

mètres in depth. The Peruvians have, for centuries past, been in the habit of using this as a manure to the sterile soil which forms the coast of their country.

At the present day, guano has become an object of very active commerce between Europe and America. This substance is, from the great quantity of nitrogen which it contains, a manure of very great value. We may distinguish several varieties of guano, which differ in colour. The white guano is the most valued; when of a red or brown colour, it constitutes an inferior quality. We owe to Fourcroy and Vauquelin the first analyses which have been made of this matter; the following are the constituents they found:—Uric acid, acetate of ammonia, hydrochlorate of ammonia, acetate of potass, phosphates of potass and lime, chloride of potassium,atty matter, sand.

Klaproth has, in like manner, published an analysis of guano. He found in it:—

Urate of ammonia	16.00
Oxalate of lime	12.75
Chloride of sodium	0.50
Phosphate of lime	10.00
Argillaceous earth and sand	32.00
Undetermined matters	28.75

100.00

More recently, M. Vauquel has analysed the same matter. A moist sample, of a yellowish-brown colour, and which gave out a urinous odour, yielded:—

Urate of ammonia	9.0
Oxalate of ammonia	10.6
Oxalate of lime	7.0
Phosphate of ammonia	6.0
Ammoniaco-magnesian phosphate	2.6
Sulphate of potass	5.5
Sulphate of soda	3.8
Sal ammoniac	4.2
Phosphate of lime	14.3
Argillaceous earth and sand	4.7
Water, traces of iron, salt, and undetermined matters	32.3

100.0

REPTILES.—The urine of serpents is found as a very thick white matter, which quickly solidifies in the air, and which is essentially formed of uric acid and the urates of potass, soda, and ammonia. We find in it, moreover, a small quantity of phosphate of lime. It does not appear to contain urea. The larger species of serpents void considerable masses of this substance, during most months of the year. Chemists often have recourse to this medium for procuring uric acid for the purpose of their experiments.

Lizards furnish a similar product.

With frogs, it is quite different. In the urine of the common frog I have found urea accompanied with albumen; we may indeed say, that albumuria constitutes the normal state of these animals.

According to Davy, the urine of the bull-frog (*Rana taurina*) is a liquid having a specific gravity of 1.003, and which contains chloride of sodium, urea, and a little phosphate of lime. That of the brown frog (*bufo fuscus*) differs from the preceding only by its containing a rather larger proportion of urea.

The tortoise, in like manner, furnishes urine containing urea.

In the mollusca, the production of uric acid has been demonstrated. So also with some insects, as the cantharides, the chrysalis of the silkworm, &c. When this chrysalis quits its shell, we see it give out a brown liquor, which consists essentially of uric acid.

PURREA (?) AND PURREIC ACID (?).—During the last few years, we have become acquainted with a peculiar substance, known under the name of *purra*. This matter was originally found in India and China, whence it was imported into England, to serve in the preparation of the *yellow prints*. It is presented under the form of rounded lumps, the weight of which rarely exceeds 100 to 120 grammes. They are brown externally; but their fracture offers a tint of a very rich orange

colour. Opinions are divided as to the origin of this matter. Some think that it constitutes a true bezoard, whilst others affirm that it is deposited, at certain periods of the year, from the urine of camels, elephants, buffalos, and other large animals, and that its formation is dependent on a peculiar alteration, which the long-continued rains effect on the food of these animals. This latter opinion is confirmed by the urinous odour which this matter exhales.

Very recently, M. Erdmann has attributed to *purrea* a totally different origin. This chemist considers this product as the mere juice of a tree neutralized by magnesia, and rendered consistent by evaporation.

Purrea is slightly soluble in water and in alcohol; its solutions have a neutral reaction, ether dissolves it sparingly: on evaporating the ethereal solution, we obtain a shining, crystalline, yellow matter, which possesses an alkaline reaction. The caustic alkalis partially dissolve it. These solutions have a very rich yellow colour. This substance leaves a considerable quantity of ashes, principally formed of magnesia, with a little potash and lime, but no phosphates.

If *purrea* be diluted with water, and a little hydrochloric acid added to the paste, there is separated from it a yellow matter which assumes a crystalline aspect. This is *purric acid*, which previously existed with the magnesia, in the form of a salt. This acid may be dissolved in the alkalis, from which it is again precipitated by acids; it is also soluble in boiling water and alcohol, and crystallizes from these liquors on cooling, thus affording a ready means for effecting its purification. *Purric acid* often retains some traces of magnesia. To purify it, M. Erdmann dissolves it with carbonate of soda, and super-saturates the filtered liquor by an excess of hydrochloric acid. The *purric acid* is deposited in crystals, which are to be redissolved in water. This solution is treated by acetate of lead; the precipitate, decomposed by sulphuretted hydrogen, is taken up again by boiling water. The crystals which are now deposited offer a slightly yellow tint. To purify them, they are to be five or six times crystallized in alcohol. After these operations, they will be found to contain but a mere trace of magnesia, which it is impossible to remove from them.

Purric acid contains:—

C ³⁰	1500	55.3
H ⁸	112	4.2
O ¹¹	1100	10.5
			2712	100.0

Purric acid, though but slightly soluble in cold water, is more readily dissolved by boiling water, and, on cooling, deposits itself in needle-shaped crystals of a pale yellow colour, which have a silky appearance. The alkalis, but especially ammonia, possess the property of colouring its solution of a deep yellow. The best solvent for *purric acid* is alcohol; ether also dissolves it with great readiness. It possesses a sweetish taste, leaving a slight bitterness behind. Its external aspect greatly resembles that of *berberine*, which is, however, less deeply coloured.

The *purrea* of commerce contains about fifty per cent. of acid. The salts of silver, lime, baryta, strontia, and magnesia, are not precipitated by *purric acid*; it, however, produces a deep yellow precipitate in a solution of acetate of lead. But a solution of this acid, when neutralized by an alkali, gives deposits with all the above salts. These precipitates are flaky, and are slightly soluble, but they do not, in general, present a uniform composition. The salt of lead, prepared by precipitating the alcoholic solution of acetate of lead by a similar solution of *purric acid*, contains:—C³⁰ H⁸ O¹¹ Pb O.

This acid, heated above 100° C., melts and partially sublimes. To effect this distillation, we may employ the method suggested by Mohr in the preparation of benzoic acid, and which consists in passing the vapour through a sheet of

brown paper, pasted over the vessel in which the sublimation is carried on. The crystals, thus obtained, are neutral, and slightly soluble in water, alcohol, and ether. Their alcoholic solution is precipitated by the subacetate of lead. They contain:—

C ³⁰	975	68.4
H ⁸	50	3.6
O ¹¹	100	28.0

They differ, consequently, by their composition and by their properties, from *purric acid*, whence they are derived.

BILE.

The bile offers especial interest, whether it be considered merely as a product of secretion, or further regarded as intervening in the act of digestion. The ancients compared the bile to soap. The researches made by MM. Berzélius and Thénard, and especially those instituted by MM. Gmelin and Tiedemann, by displaying a numerous series of products derived from the bile, had gradually effaced the simple idea which had been formed of the nature of this liquid, when M. Demarçay, a few years back, was led to revert once more to the opinions announced by the ancient chemists.

M. Berzélius, more recently, published a long work on the bile, in which he called the attention of chemists to several acids and new bodies furnished by this liquid on analysis, whether it be that they pre-exist in the bile, or that they result from the various and ready metamorphoses of the essential principles of this secretion.

We shall, in our observations, follow up the views of M. Demarçay, which have since been confirmed by M. Liebig, and also, to a certain extent, by the still more recent experiments of MM. Theyer and Schlosser.

The bile is a viscous, ropy liquid, usually of a deep green colour; it taste is at first bitter, leaving an insipid, sweetish flavour behind. It is dissolved by water and forms a kind of lather, as does soap. It is often rendered thick by mucus, which becomes partly precipitated, whilst another portion remains in solution; hydrochloric and most other acids, if added in but very small quantity to the bile, will completely precipitate this matter; it is in fact foreign to its constitution, and is only found there accidentally. Bile does not coagulate by ebullition.

If we except some few principles, which may be regarded as merely accessory, the bile is essentially formed by the combination of a peculiar azotized acid with soda: that is to say, of a *choleic acid* of soda. It owes its coloration to a green matter, mixed with a yellow principle which, probably, is only a modification of the former. If this colouring matter be treated by nitric acid, it produces a characteristic reaction. The liquor, at first green, becomes of a violet-blue, then red, and this change is accomplished in the space of a few seconds. The red colour, in its turn, shortly disappears to give place to a yellow tint. This reaction is so marked that it serves not only to characterize the bile, but also to discover the presence of this liquid in the urine or in other products of excretion. The coloured solutions of bile may be perfectly decolorized by means of purified animal charcoal, or else by carefully adding baryta water, which precipitates the colouring matter from them.

The bile contains the saponified and the non-saponified fatty matters which are met with in the animal economy; cholesterine also exists in it in small quantity. To extract this principle, we have merely to agitate the decolorized bile with twice its volume of ether, which takes up the cholesterine; we may now obtain it from this menstruum by evaporation under the form of white and shining scales.

The bile also contains some salts: if it be incinerated after dissolving it in alcohol, the greater part of the saline residue is found to be composed of carbonate of soda. It also contains some phosphate of soda and a slight quantity of chloride of sodium, with traces of salts of potash and iron. The following is the composition of

the bile in the ox, reduced to its most simple expression:—

Water	875.0
Choleate of soda	110.0
Colouring matters, different fatty matters, mucus, &c.	5.0
Diverse salts	10.0
	1000.0

All the phenomena which the bile presents on contact with different reagents, are due to the choleate of soda which constitutes its base. On evaporating it to dryness, and acting on the residue by alcohol, we shall find this menstruum dissolve the choleate of soda with the fatty and colouring matters, whilst it leaves the albuminoid matters and some salts behind. The alcoholic solution becomes decolorized when treated by animal charcoal. If this solution be evaporated to dryness and reacted on by ether, this agent will remove the cholesterine and the fatty matters. When deprived of its fatty and colouring matters, the bile furnishes by desiccation a solid, friable mass similar to gum arabic. It is completely redissolved by water and by alcohol, communicating to them a very feeble alkaline reaction. The bile, when dried and pulverized, quickly attracts moisture from the air. Incinerated on a platinum plate, it leaves a residue composed essentially of carbonate of soda mixed with a little chloride of sodium.

The aqueous solution of bile is not clouded by oxalic or acetic acids. Hydrochloric acid throws down a resinous precipitate, and robs it of its soda. The nitrate of silver forms with it a plastic deposit, white at first, but which quickly turns brown. The neutral acetate of lead produces a flaky white precipitate: the supernatant liquid assumes an acid reaction; if this liquor be poured off from the precipitate, we may obtain a second deposit by the basic acetate of lead. The subacetate of lead precipitates the bile completely, the liquor retaining in solution but a small quantity of organic matter; an excess of the salt of lead redissolves a portion of this precipitate. The salts of baryta occasion no cloudiness in it; the same may be said of lime-water and of the chloride of mercury. The perchloride of iron forms with it an unctuous precipitate of a brown colour. The chloride of tin throws down the whole of the organic matter in white flakes.

The alcoholic solution of bile undergoes very analogous reactions to those experienced by the aqueous solution; only, as the lead precipitates are more soluble in alcohol than in water, the neutral acetate of lead forms no deposit with it.

Bile, in its pure state, contains:—

	Kemp.	Enders- lin.	Theyer and Schlosser.
Carbon	58.16	58.16	59.9 58.28
Hydrogen	8.30	8.81	8.9 9.20
Nitrogen	3.70		
Oxygen	22.61	25.76	
Sodium	0.53	0.53	
Chlorine			
Sodium	0.37	0.51	

Choleic Acid.—Several processes have been proposed for obtaining this body in a state of purity. According to M. Demarçay, the alcoholic extract of bile should be dissolved in 100 parts of water, and to this should be added two parts of sulphuric acid, diluted with ten parts of water. The whole is then to be heated in a water-bath. When some oily drops appear upon the surface, the pan is to be withdrawn from the fire. In about eight or ten hours, the choleic acid will be found to have separated under the form of a green magma. The liquor is to be decanted, filtered, and evaporated, so as to obtain a further quantity of choleic acid; this operation should be repeated until the solution is reduced to a fourth of its volume. The deposits, after being washed, are dissolved in alcohol, and treated by a few drops of baryta water, which separates from them the sulphuric acid. The filtered solution, being evaporated to a syrupy consistence, is agitated with ether, which removes the fatty matters. The residue is evaporated in a water-bath, and placed, while hot

in vacuo. Thus prepared, it still retains the whole of the colouring matter, and a small quantity of soda and baryta.

The second process consists in decomposing the precipitate formed by the bile with the salts of lead, taking the precaution to put the salt of lead in excess, and then to add ammonia to it. The precipitate is to be heated to melting, washed, and then acted on by boiling alcohol, which dissolves an acid salt, but leaves behind a basic salt as well as a combination of oxide of lead with the colouring principle. The alcoholic solution, being treated by sulphuretted hydrogen, gives, after filtration and evaporation, a brown magma. This mass is to be dissolved in the least possible quantity of alcohol, and then agitated with ether, which removes the fatty matters. The residue is acted on by cold weak alcohol, after which it is evaporated, and the residue dried as before.

M. Liebig has given the following process:—In an alcoholic solution of eight parts of dried and purified bile, dissolve one part of oxalic acid; the mixture is then heated to ebullition; after which it is to be set aside for ten or twelve hours. During the solution of the acid, there is immediately separated a mass of fine white crystals of oxalate of soda. As soon as this deposit has ceased to take place, the liquid is to be filtered, diluted with a little water, and digested upon carbonate of lead. The filtered liquor is now treated by sulphuretted hydrogen, and the solution evaporated to dryness in a water-bath.

MM. Theyer and Schlosser precipitate the bile freed from mucus and fatty matters by subacetate of lead. The deposit is heated with water to the boiling point, and treated by sulphuric acid until it has lost its adhesive consistence. The liquid is then filtered, and the lead, remaining in solution, separated by sulphuretted hydrogen.

Dry choleic acid is a solid body, of a slightly yellowish colour, friable and pulverulent, and which quickly absorbs atmospheric moisture, so as to form an agglomerated mass. Its taste is bitter, and its dust strongly irritating to the mucous membrane of the nares and the throat. It is readily dissolved in alcohol, but very sparingly in ether. When recently prepared, it is with considerable readiness taken up by water; but, after a short time, this solution thickens, and deposits the greater part of the acid; it still, however, retains sufficient to preserve its acid reaction, and that bitter taste which is so characteristic of choleic acid (Demarçay).

According to Liebig, the aqueous solution of pure choleic acid remains limpid for several days. It decomposes the carbonates. Acetic acid does not precipitate it; dilute hydrochloric and sulphuric acids render it milky, and give rise to the formation of oleaginous drops, which adhere to the sides of the vessel. An excess of acid removes this cloudiness (Liebig). Heated on a platinum plate, choleic acid melts, puff up, burns with a fuliginous flame, and produces a slight carbonaceous residue, which is eventually wholly consumed. By analysis, it yields the following results:—

	Demarçay	Dumas	Theyer and Schlosser.
Carbon	63.82 63.71 64.57	63.5	63.70 63.76 63.98
Hydrogen ...	9.05 8.82 8.85	9.5	8.84 8.50 8.58
Nitrogen ...	3.31 3.26 ..	3.3	3.97 3.45
Oxygen and Sulphur (a)	23.78 24.22 ..	23.9	23.49 24.29

(a) Sulphur has not hitherto been pointed out in choleic acid; but the recent experiments of M. Redtenbacher on the composition of taurine—a substance derived from choleic acid—place beyond all doubt the existence of sulphur in this acid. In the liquid bile, which contains no traces of sulphate, I have found 0.19 per cent. of sulphur, whence it would result that choleic acid must contain about 2 per cent. of this element.

They calculate that in France from twenty to thirty are annually interred alive, computing from the number of those who, after supposed death, come to life before the funeral is completed.

ORIGINAL CONTRIBUTIONS.

ON THE PHYSIOLOGICAL AND PATHOLOGICAL CAUSES OF SUDDEN DEATH IN CONNECTION WITH THE VASCULAR OR CIRCULATORY SYSTEM.

By MALCOLM W. HILLES, Esq.

(Continued from p. 113.)

SECTION II.

We now come to the consideration of cases of sudden death produced by derangement of some portion of the circulatory apparatus.

It may be supposed that we are principally indebted to modern observation for our present knowledge of the phenomena, both physiological and pathological, attendant on these cases. Until the discovery of our countryman, the immortal Harvey, who first pointed out the true course of the circulation of the blood, and the uses of the several parts engaged in the transmission of this fluid to and from the various parts of the body, no satisfactory conclusions could possibly have been arrived at upon the subject; observation, it is true, might have recorded the facts daily brought to light, but these were rendered comparatively useless by the false theories that were raised upon them, and thus tended to distract rather than to direct the judgment; all was comparatively a chaotic mass of observations, conjectures, and conclusions; the first alone being correct, but serving only to expose the darkness and the folly of the others. And yet Harvey was not believed—was ridiculed and slighted when he first propounded his great discovery; for many years this great man laboured against the prejudices of the learned of the day, and encountered the most irrational opposition before he succeeded in establishing the truth of his doctrine; he had at last, however, the proud satisfaction of enjoying a triumph, the labours to attain which had wellnigh consigned him to his grave in poverty and contempt. And yet his cause was that of truth against error.

The study of the circulatory system in man is one of the most interesting that can be pursued, and would well repay the labour of many years spent in the investigation of the structures and functions connected therewith.

To the *physiologist* it unfolds the material origin of our being—the source from whence, in youth, we increase in size and strength; in adult age, derive the maintenance of the organs of human life, and the integrity of the human functions; and in age, the elements of disease, which, sooner or later, bring the fabric it has raised and nourished once more to the elements from which it sprung.

To the *pathologist* and *medical practitioner* it reveals the causes of many of the most important and interesting diseases to which mankind is subject, and exhibits a general influence in almost all the affections of human nature.

To the *natural philosopher* it discloses the only perfect hydrodynamic structure that has ever been formed, and holds out to the diligent mechanic a model from which to derive the most useful knowledge regarding the laws which regulate the circulation of fluids. Strange as it may appear, it cannot be questioned that the heart blood-vessels contain the groundwork of many of the improvements that have recently taken place in hydraulic machinery, and in more than one instance still presents a perfection of structure that has not been realized, and might well be imitated, by modern art.

It is unnecessary for me to enter here upon a description of the circulatory apparatus; it will be sufficient to state that it consists of a central organ or engine, the heart, and two sets of conduit pipes or vessels, the arteries and veins. The office of the heart is to propel alternately the blood, to receive it from all parts of the body, including the lungs; that of the arteries is to conduct the pure or arterial blood to such parts; whilst the office of the veins is simply to carry back the blood from those parts to the heart. These duties of arteries and veins are transposed

in one instance in the adult—namely, in the pulmonary circulation, where the pulmonary artery carries the impure blood from the heart to the lungs, and the pulmonary veins convey the oxygenated or pure blood back again from the lungs to the heart.

The universal presence of circulatory vessels in organized beings shows the necessity of their existence; indeed, the growth and maintenance of bodies without such sources of nutrition can hardly be conceived.

The presence of circulatory vessels is as necessary to functional as to organic existence, no organ being capable of performing its function without a due supply of the circulating fluid. This fact is well illustrated by the effect produced on the brain by the loss or sudden abstraction of blood: fainting immediately results, which is an instantaneous suspension of the functions of this organ from want of its proper supply of blood.

Numerous facts prove that it is almost of equal importance to other organs. When the arteries leading to a limb or other part are tied, partial or complete paralysis results; and, although this is not so well marked as in the case of the cerebral organ, it is sufficiently so to sustain our position, especially when we reflect that the ligation of one artery only partially arrests the flow of blood to the part. Who can doubt what would be the result if all the arteries leading to an organ were tied? Certainly, arrest of function first, then of organic existence, and finally mortification and death.

But organic existence may be maintained with an arrest of function; the stomach, liver, kidneys, &c., afford numerous instances of such; this observation, however, has but little connection with the influence of the blood on the functional and structural integrity of the various organs of the body.

This evident and universal influence of the blood on the life or integrity of the individual parts, or whole, was so well known to the ancients as to induce many of their first philosophers to regard it as the seat of the living principle; hence the term “sanguis” was used to designate both the blood and the life, as in the following passage:—

“*No judicio iniquo exsorbeatur sanguis tuus.*” —“Cicero de Orat.,” i., 52.

Modern physiologists, however, regard the blood solely as the vivifying material which maintains and supports life, in the widest acceptance of this term, and leave the question of the centre of life in the human body, where it will most probably ever remain, to conjecture. I must observe here, although I do not desire to enter upon a metaphysical inquiry, that much more appears in modern works on this subject on the attempt to establish the identity of the living principle with the spiritual existence of man: of the latter we can form but a most imperfect idea; the former is evident to us, and may be studied, *per se*, with advantage.

The undisputed influence of the vital fluid on the functions of the brain is of the first importance in our inquiry, as it serves to explain the extremely sudden death which invariably results in all cases where, from some defect in, or disease of, the organs of circulation, a large quantity of this fluid is rapidly lost.

In treating of the subject of sudden death, connected with the respiratory organs, we shall divide our present inquiry into—

1. Cases of sudden death produced by, or the consequence of, disease of some portion of the circulatory system.

2. Cases of sudden death occurring from derangement of some portion of the circulatory system, where disease is either absent, or has not contributed to the result.

Of the different structures which are engaged in the circulation of the blood, it might be reasonably supposed that the heart would be most frequently diseased, and its diseases the most productive of sudden death.

The constant action of this organ—no remarkable from the first to the last moment of exist-

ence, pulsating without rest even for a small portion of a minute, and the force which it is known to exert in order to overcome the obstacles of the circulation, in even the healthy state—would lead to such an inference.

This, however, is not the case; although diseases of the heart are frequently met with, and are usually productive of sudden death, this organ is much less subject to disease than the arterial system, which is comparatively passive in the circulation of the blood. That portion of the heart, namely, its muscular structures, which are exclusively occupied as the active agents in the circulation, is indeed seldom diseased, unless, as the consequence of disease, in some other portion of the circulatory system.

On this point M. Bertin goes so far as to contend that dilatation, which is the form of disease most frequently found in the muscular structure of the heart, is never a *primitive* malady, but always the result of some obstruction to the circulation.

Although M. Bertin's opinion is not correct, there can be no question that disease of the muscular structure of the heart, *a priori*, is of extremely rare occurrence. Rheumatism, perhaps, affords the best example of independent disease of the muscular fibres of the heart.

The valves of the heart and the large arteries connected with this organ, especially those on the left side, are usually the seat of the primary disease. This, once established, soon leads to an increased development or hypertrophy of the muscular tissue of the heart itself, which, although usually regarded as a morbid result, is really a sanatory provision of Nature, and intended to overcome the resistance or obstacle caused to the circulation of the blood by the irregular action of the diseased valves. But this attempt to remedy the effects of the diseased valves upon the circulation leads to its further derangement, as the enlarged heart produces, both by its unusual power and size, a series of symptoms not previously present. The valvular disease continuing also to increase, a morbid condition of the heart and general circulation results, which is inconsistent with the maintenance of health and life, and leads to a fatal result.

Confining our observations, for the present, to diseases of the heart, it is not surprising that almost all these affections have a tendency to a *suddenly fatal termination*; as it requires only a more than usually disturbed action of the parts, or a greater interval in the pulsation of this organ than generally occurs, to cause a failure of the proper supply of blood to the vital organs of the body, especially the brain and nervous system; the result of which is the cessation of their functions, the loss of sensibility, fainting, and death.

At first, these attacks are not alarming; the patient, perhaps, is subject to fainting fits, but recovers from these in a little time. Here, the energy of the heart is tolerably perfect, and the nervous system is not seriously impaired; both, therefore, aid in restoring the heart's action, re-establishing the circulation, and resuscitating the patient; but, in the more advanced forms of the disease, the innate irritability of the heart, and the nervous energy, become so enfeebled that, on the accession of a fainting fit, they fail to set the machinery in motion, and sudden death is the consequence. In these cases death is produced in the following order:—1, irregular action of heart; 2, impaired and suspended nervous energy; 3, paralysis of heart; 4, death. But enlargement or hypertrophy of the heart is frequently productive of sudden death in other modes. Thus, for example, the *vital organs*, or *great centres of life*, may become so congested with blood as to be incapable of performing their functions; death, is, therefore, the result: its degree of suddenness being in proportion to the rapidity and extent of the congestion, and the parts more immediately affected. In the brain this congestion produces an apoplectic attack; in the lungs, pulmonary congestion: affections, as we have already seen, frequently productive of sudden death.

Other organs—indeed the whole vascular system of every part of the body is liable to the same congestion; but here the symptoms are less severe, and seldom produce a sudden termination.

It may be well to observe, that these congestions are too frequently regarded as the immediate consequence of the increased action of the heart, which propels the blood with unusual violence to the capillary vessels; and a mode of treatment is based thereon which is certainly inconsistent with the true pathology of congestion.

The cause of the congestion is, I consider, not an increased but a diminished flow of blood through the capillary system, the result of the influence of the heart's action being cut off from these vessels by the mechanical obstacles existing in the valves, or elsewhere, and of the obstruction to the return of the blood to the heart, effected by the over distended state of this organ.

In these cases, therefore, we have the apparent anomaly of violent action of the heart, and a diminished circulation. That the circulation is diminished in such cases is evident from the feeble action of the arteries, the congested state of the capillary vessels, the coldness of the superficial parts, the tendency to edema, &c.

I feel that this view of the state of the general circulation, in cases of hypertrophied heart, is not sufficiently impressed on the attention of the profession, although I consider that it is the correct one, and that in very few instances, indeed, of hypertrophy of the heart—that is, the left ventricle—have we an increased energy of the circulation. Some will state that such must be the case where the left ventricle is hypertrophied, and there is no disease of the aortic valves or other apparent obstruction to the circulation; but I think I shall be able to show that, even in these instances, there is often hypertrophied heart conjoined with a diminished general circulation.

That the profession generally consider the circulation to be active in these cases is apparent from the following extracts.—

"But M. Bertin is not, in our opinion, supported by sound observation when he says, that serous infiltration, and the whole class of symptoms bespeaking an obstructed circulation, are totally foreign and repugnant to hypertrophy. The truth we believe to be that the very same energy of the circulation which gives rise to active hemorrhages, apoplexy, &c., causes, as its next effect, engorgement of the arterial capillary system; the necessary consequence of which is serous infiltration, and more or less of all the other symptoms indicative of obstructed circulation."—"Cyclopaedia of Medicine," art. "Hypertrophy of Heart," p. 540, by J. Hope. And again (same page)—"which impediment co-operates with the increased energy of the arterial circulation," &c.

How far does our treatment of such affections, by blood-letting, digitalis, and other means, by which the heart's action is lessened, consist with this view of the physiological and pathological causes which produce the congestion of the capillary vessels? If we moderate or lessen the heart's action, shall we not thereby induce further congestion?

Notwithstanding these observations, I believe that such treatment is the most appropriate that can be devised at present, as it relieves the patient of the most distressing of his symptoms—the violent action of the heart, and, by lessening the quantity of the circulating fluid, tends further to the relief of the capillary congestion.

At the same time, our attention should be directed to this view of the cause of the congested state of the capillary vessels, and such remedies I resorted to as may promote the circulation in these, independently of the heart's action.

There is one condition of the arterial system which, occasionally, leads to an increased action, and hypertrophy of the heart, but which is rarely noticed by the profession. I allude to a

deficiency in the elasticity of the aorta and large blood-vessels, somewhat analogous to a paralysis of the muscular tissue.

When we reflect on the important influence which the elasticity of the arterial system exerts on the circulation of the blood, we must expect that any deficiency of this elastic power will throw an additional duty on the heart, and thus lead to hypertrophy.

The principal uses of the elasticity of the larger arteries are—1. To receive, and thus moderate, the impulse of the left ventricle, which would be highly injurious to the vital organs, were it propagated to their vessels by means of rigid tubes. 2. To react on the blood propelled into the aorta and other large arteries, so as to empty these partially, and keep the blood itself in motion; when, therefore, the left ventricle of the heart again contracts, it meets with the arteries in a fit condition to receive the blood, and its force is not expended in overcoming the inertia of this fluid that would attach to it if in a state of rest, the elasticity of the arteries having maintained it in a state of motion during the intervals between the contractions of the heart.

If we suppose the elasticity to be impaired, lost, or destroyed, from organic changes in the coats of the vessel, as occurs in more advanced life, or from congenital malformation, or other cause, we may trace the results that must ensue.

If the arterial tissue be more yielding than in its normal state, the force of the left ventricle is lost by the distention of the aorta, and is not propagated to the distant or capillary arteries; and again, when the period arrives when the aorta should react on the blood, the elastic power is wanting, and this fluid is not propelled from the interior of this vessel as it should be: this consequence is, that the left ventricle, when it contracts, meets with a large column of blood in the principal arteries in a comparative state of rest; it is obliged, therefore, to contract more violently, and, therefore, irregularly, to overcome the inertia of this column, and propel it to the more distant parts of the body. This violent action soon leads to hypertrophy of the heart, and such an increased action of this organ as to further render the impaired elasticity of the arteries less able to resist its impulse, and thus aggravates all the original evils and their attendant symptoms. In this we may have hypertrophied heart without apparent disease, and yet a deficient general circulation.

The rigid state of the vessels, in advanced life, tends to similar results, although, from an opposite condition of the arteries, the state of the column of blood in the aorta is precisely similar.

To this circumstance may be occasionally attributed ruptures and diseases of the semilunar valves, which are so frequently met with, these having to sustain a much larger column of blood than natural.

To it also may be ascribed much of that irregularity of the general circulation, and of the heart especially, which is so frequently met with in advanced life, and which is often treated as a local affection dependent on the cerebral circulation, and as having no connection with any abnormal condition of the larger arteries.

My attention was first directed to this subject, many years since, from observing enlargement of the left ventricle in a youth in whom there existed no apparent organic disease in the valves or arteries, or indeed any other manifest abnormal structure. It occurred to me, then, that a deficiency in the elasticity of the arteries would satisfactorily account for the enlargement of the heart; and it appeared to me, from examination, that the aorta was less elastic than usual. To ascertain this correctly, however, would require more numerous experiments and extensive observation than I have been able to apply myself to. At that time I considered this disease of the arterial system to have been unnoticed by medical writers, but I have found that Mr. Hodgson, in

disease, without the occurrence of any other accident, tubercles are invariably found in the lungs after death."

Here, then, are individuals with sound lungs, in whom the development of tubercles may be foretold. Therefore, as we now know the nature of diabetes, we may, for this particular case, arrive at a positive etiology of the tubercular affection.

In what does a diabetic patient chiefly differ from a man in health? More particularly in this, that in the healthy person, the feculent food dissolved in the digestive apparatus, and carried slowly into the circulation, is there completely consumed, no trace of it being afterwards found either in the feces or in the urine; whereas, in the diabetic, the feculents, rapidly converted into glucose in the stomach, are immediately absorbed; and this glucose, being in too large a proportion in the circulating apparatus to be normally destroyed, becomes eliminated by the kidneys. Hence there are three important circumstances which distinguish the diabetic from the healthy individual, viz.:—1, the perversion of the functions of the stomach, causing a rapid solution of the feculents; 2, the existence of a large quantity of glucose in the blood; 3, great activity of the secreting organs of the urine to get rid of the glucose. Important consequences proceed from these differences.

The active powers of the digestive organs, and the secreting apparatus of the urine, are uselessly employed for the support and repair of the animal economy. The nature of the transformations which the nutritive fluid is continually undergoing is modified by the presence of a considerable proportion of glucose in the blood. The food dissolved in the digestive apparatus being no longer usefully employed, the patient is supported at the expense of himself; hence the emaciation and wasting, with all its results. Now, the necessary effect of this anomalous condition is the spontaneous production, and the localization of the lungs, of tubercular globules, which eventually, by their successive agglomeration, invade this organ and prevent its important functions.

The causes of the spontaneous evolution of tubercles for this particular condition are thus clearly established:—

1. Perversion in the digestion of feculents.
2. Presence in the blood of a variable proportion of glucose.
3. Elimination of the glucose by the kidneys.
4. Replacing the glucose eliminated, by the slow destruction of the fundamental principles of the blood, the muscles, and the other organs.

May not analogous circumstances be met with in the different conditions under which tubercles become developed in the lungs or in other organs?

Apart from these cases, in which tubercles are developed as the result of the perversion in the digestion of feculents, can we not easily understand that other perversions in the important function of nutrition may cause the development of the tubercular affection? I hope, when our great work on digestion is completed, to be able to return to the nature of these perversions, which may be suspected after what we have published. I think, therefore, it would be of the greatest importance to make some careful and accurate investigations into the manner in which the digestion and the assimilation of the different aliments takes place in persons in whom phthisis has just commenced, or who are threatened with this disease. We should then establish an equation, as I have done with respect to diabetes; the food and drink would form its first term, and the principles contained in the feces, the urine, and the other products of secretion or otherwise, the nature and quantity of which could be appreciated, the second. These investigations would lead to results equally precise with those I have obtained in diabetes. We may resume the contents of this paper in the following propositions:—

1. The cause of the development of tubercles in the lungs of diabetes is a defect in nutrition and assimilation.

2. The tubercular affection has its origin, much

more frequently than is imagined, in a defect in nutrition and assimilation, which cannot be known, and which can only be remedied by establishing an exact balance between the ingesta and the excreta.

3. It likewise originates in the excessive, continued, and unrestrained losses of fluids that are essential to the economy.

4. When a patient becomes emaciated it is important to ascertain as soon as possible the cause of the emaciation, and to remedy it; we should thus alter the conditions which give rise to the spontaneous evolution of the tubercular globules.

19, Langham-place.

A COMPARATIVE VIEW OF THE HEART AND OTHER ORGANS.

By W. H. BROWN, M.D., F.R.S., &c.

(Continued from p. 87, vol. 15.)

PAPER II.—THE LUNGS.

Although in my previous paper on the Heart, the whole of the present subject is foreshadowed it is nevertheless an equally interesting and instructive matter, with that of my former communication, to take a comparative view of the respiratory apparatus, and trace its double perfecting in the denizen of the land and of the water.

SUB-KINGDOM RADIATA.

Porifera.—As in the sponge there is no circulating fluid, but its growth is altogether of a low vegetable or fungus order, so is there in it no respiratory system; but whatever influence the air may exercise on its tissues, it obtains general access to them in the constant currents of water that pass into its substance.

Polypifera.—No distinct organ is as yet evolved, or part appropriated to the carrying on of the respiratory function. If the air, therefore, act in any way upon the nutrient fluid, it must do so generally through the superficial tissues of the body, both external and internal.

Acalephe.—It was stated, when speaking of the circulatory system of this class, that in the medusa the digested food was conveyed from the globular stomach through several vessels to the margin, where these vessels ramified and exposed their contents to the action of the air contained in the water. This, then, is, as we may say, the first localization of the function in the animal kingdom. From their progressing by collapsing and distending this branched margin the medusa family of the class *acalephe* have been distinguished by the term *pulmonigrada*.

Echinodermata.—In the whole of this tri-l respiration is a purely peritoneal function—that is to say, the vessels ramifying on the lining membrane of the shell are those in which it is carried on, a constant current of water being kept up through a series of short tubes opening on the exterior of the animal.

SUB-KINGDOM ARTICULATA.

Annelida.—In this class we have both water and (if the term be allowable) amphibious breathers. In the latter, the function is carried on principally in two ways—one, by means of ten or twelve sacculi opening by short ducts on either side of the animal; the other, by the whole cuticular surface. The activity of the function in the latter part seems to be in the ratio of its performance in the former; that is to say, when the air-cell or proper respiratory cavity is not imparting a sufficient amount of the purifying principle to the blood, it is sent in greater quantity to the surface of the body, where it undergoes the necessary change. The leech and earthworm belong to this division of the class. In the first division, or water-respirers, short feathery tufts are given off with the loco motive organs at every ring on both sides of the body, or in those inhabiting a shell a large tuft is developed round the head of the animal. We have then presented to us in this class both rudimentary lungs and gills—the first in the induplicate of the external surface or air-cell; the latter, in the cuticular prolongation or tuft.

Insecta.—The beautiful mechanism of the

respiratory function in these ever-active little denizens of the air is as follows:—On either side of the body, in the membrane which connects the hard segments that incase it, are ten minute pores or apertures, termed spiracles; these are the entrances to slender tubes (tracheae) which ramify—here and there dilating into air-cells or cavities—through the entire body. The first thing in this arrangement worthy of notice is the situation of the spiracle; had it been on the hard integument, its closing, so necessary at times for the preservation of the animal, would have been impossible; but where it is its sphincter is of course well capable of acting. (In those species which pass their lives upon the ground or in the earth, the spiracle is fringed with hair, which filters the air from the fine particles of dust which otherwise would gain access with it.) Then, with regard to the tracheae, one cannot but be struck with the brilliant adaptation we find to admit of variation in their calibre: for it need hardly be remarked that these tubes, passing through the whole organism of the body, could not maintain a uniform volume without occasioning derangement; the necessary change in this then is effected by means of a spiral thread, which is closely coiled up between the exterior and interior membranes of the tube, and may be traced even into the most minute of them. We readily perceive how much is gained in the great purpose of lightening the body by this description of respiratory mechanism—the air flowing so entirely through the body necessarily decreases its specific gravity considerably—a system of vessels, too, for the circulation of the blood, is entirely dispensed with. The general aeration of the blood, moreover, endows the insect with its characteristic strength and activity. The abdomen contracts and expands regularly from twenty to sixty times in a minute, in different species, for the admission and expulsion of the air.

Arachnida.—In the lower members of this class respiration is carried on by a similar apparatus to what we met with in the preceding class. In the higher members, however, the spiracles—six or eight in number, and opening on the ventral surface of the body—admit the air into sacculi, ranged along their respective sides. These are not simple cavities, as in all our previous instances, but cavities presenting many induplications (which, indeed give them an appearance not very dissimilar from that of the interior of a poppy), so that a greater quantity of blood may be presented to the atmosphere than would otherwise be the case. This gill-like development of the organ has caused it to be denominated a pulmonary branchia; and when we consider that the habitat of the animal is, generally speaking, in a very damp atmosphere, the term will not seem so far-fetched.

Crustacea.—The respiratory function is very variously performed in this class. In the lowest species it is carried on by the entire surface of the body. In a tribe above this, the last joint of the legs (fimbriated for the purpose) performs the function. Higher still in the class, the tail performs the duty of progression, and the legs are entirely devoted to the office of respiration. In the crab and lobster tribe, at the head of the class, regular branchial tufts are evolved on each side of the chest (consisting of laminae covered with horizontal filaments), which are incased in the hard envelope of the body, leaving an aperture above and below them for the admission and expulsion of the water; for the maintaining of a constant current of which a curious contrivance had recourse to, in the development of a flacellum, or flap, attached to some part of considerable motion, the action of which forces the water through the gill-apertures.

SUB-KINGDOM MOLLUSCA.

Tunicata.—The respiratory function in this half-annulated race is carried on entirely in the peritoneal lining of the capacious pouch which contains their viscera. The entrance to this chamber (a perforation at the top of the animal) is carefully guarded by a fringe of tentacles, which effectually prevents the entrance of any

improper substances. The renewal of the water is amply provided for by cilia; and in some species the admission and expulsion of the water from the peritoneal cavity is their only means of progression.

Conchifera.—The branchiæ of these bivalves consist of four frill-like bodies given off, between lips of the mantle, at the anterior circumference of the body, composed of cellular tissue traversed by innumerable parallel capillaries, which expose a large amount of blood to the renovating influence of the water; a constant current of which is maintained—and this, in the direction of the mouth of the animal for its nutriment—by the incessant action of countless vibratile cilia which cover the branchiæ. The action of these is so strong, that, when a piece of the gill is snipped from the living animal and thrown into water, it rows itself in a definite direction for a short time.

Gastropoda.—The snails and other air-breathers of this class have an air-chamber of somewhat triangular form in the back, into which there is an opening for the admission of air, on the right side of the animal. The mechanism of this cavity is as follows:—The delicate membrane lining the roof receives the blood for aeration, whilst the floor consists of a muscle that separates this cavity from the other viscera, and keeps up a constant movement, like that of our diaphragm, for the admission and expulsion of the air. The apparatus of the water-respirers of this class is variable, both as to shape and position: in one tribe, the gills have a beautiful flower-like appearance, and are arranged round the anal orifice; in another tribe, they are delicate pinnated frills situated on both sides of the animal; in a third, a similar organ is confined to one side, and is covered by a process of the mantle; and in a fourth, a perfect chamber is made for them in the anterior part of the animal, from the roof of which they hang suspended in from one to four rows, due provision being made for the admission of the water. As in many other classes the air-breathers are not confined entirely to terrestrial life, but, on the other hand, pass much of their time in the water, in these there is necessarily an ability to close the pulmonary orifice, and they are obliged to come to the top of the water frequently, to replenish the air contained in the respiratory cavity.

Pteropoda.—The respiratory function of this little-examined class was pretty positively asserted by Cuvier to be carried on by the fins given off from the neck, with which they row themselves through the water. This statement, however, has been as positively denied by Eschsch. If the function be not confined to this spot, it doubtless participates in its performance with the whole surface of the body.

Cephalopoda.—The branchiæ of this class, one on each side (two in the nautilus), consist of long, tapering, leaf-like bodies, attached by the stem, which is composed of the branchial artery and vein, whilst the lamellæ, given off at right angles with the stem, are formed of the reticulated capillaries—in which the blood undergoes its change—ramifying through cellular tissue. These organs are separated from the other viscera by a membranous septum. The muscular action of the walls of their apartment draws in a current of water through a valvular process of the mantle, and expels it, along with the feces—the rectum opening within the septum—through the funnel—a cylindrical process of the mantle. The expulsion of the respired water is a means of progression with some genera of the class.

SUB-KINGDOM VERTEBRATA.

Pisces.—On each side of the cavity of the mouth in fishes stretch several (most commonly four) bony arches, termed branchial arches—each consisting of several pieces of bone, and presenting the concave surface to the mouth. From the convex surfaces a double row of leaf-like membranous processes (consisting of the aerating capillaries, ramifying through cellular tissue), edge to edge, are given off. The branchial

artery and vein lie in a groove on the convexity of the arch, the former superior to the latter. The arches are toothed on their concave surfaces to prevent the passage of the food into the gill-cavities. By the action of the muscles of the mouth a constant current of water is maintained over the gills; which, of course, enters at the mouth, and makes its exit in osseous fishes at the operculum or gill-covers, in artilaginous fishes (where the gills are more perfectly enveloped), through several small apertures in the neck, termed branchial openings. What part the air-bladder of fishes plays in their respiration is by no means satisfactorily demonstrated; it would certainly seem that where it has a ductus pneumaticus, particularly opening in the throat, as it does in some species, it exerts some influence over the respiratory process; but when it is a perfectly closed cavity, without any channel of communication between it and any other organ, it is impossible that it can act in any other way in the economy than as an increaser of specific gravity on compression, or diminisher of it on distention.

Reptilia.—The lungs of reptiles consist of one or two membranous bags, lying loose among the general viscera of the body. The aerating surfaces of these cavities are much increased by numerous septa that divide the upper portion of the lung into many compartments. The trachea, which consists of higher classes of animals of cartilaginous rings, enters the lung immediately, without previously subdividing into bronchial ramifications. Having no diaphragm, and altogether a very imperfect inspiratory and expiratory system, the majority of these creatures are obliged to take in air by a swallowing process; that is to say, the mouth being full of air and closed, and the posterior nares so valved as to prevent its return through the nostrils, the muscles of the mouth and neck force it through the larynx into the lungs, whence, when it is deteriorated (which necessarily is a much longer process than in other animals), it is expelled by means of muscular action. Its expulsion in the serpent tribe produces the hissing sound peculiar to them. Some reptiles, as is well known, commence existence as fishes (the tadpole, which afterwards becomes the frog, for instance); we have in these, of course, a metamorphosis of the respiratory apparatus, inasmuch as the branchial tufts at the side of the neck get gradually covered in like the gills of the fish, until the operculum ceases to be such, and the tufts are entirely absorbed; during which changes the membranous lung has been developing in the ratio of the former's withdrawal, and the pulmonary arteries have gradually increased in calibre as those of the branchiæ have become obliterated. A third variety in the breathing apparatus of reptiles is found in the perennibranchia, or true amphibious tribe, which are provided with both branchial tufts (uncovered) and proper reptile lungs, either of which aerate the blood, as the animal may be on the land or in the water.

Aves.—The lungs of birds better deserve to be so designated than those of any other creature hitherto considered, consisting as they do of two highly vascular, well-formed, spongy masses. The trachea, opening at the root of the tongue, consists of perfect cartilaginous rings, and possesses both an upper and a lower larynx: it is in the latter, situated at the bifurcation of the bronchi, that the brilliant modulations of sound peculiar to the race are effected. Several of the subdivisions of the bronchus open into the lung, but the principal one passes through its substance (for it is not in it alone that the aëration of the blood takes place), and opens among the viscera, the whole serous lining of which, and continuation into the interior of the bones and numerous saccular developments under the integument, are concerned in the respiratory function. Not that this is the sole purpose gained by this wonderful extension of surface, for, of course, it eminently contributes to lessen the specific gravity of the bird—a most important matter in its economy. It likewise affords an excellent leverage for its muscles; and it is to this circum-

stance (the extent of pulmonary surface) that the bird is enabled to prolong its note to the extent it does. The lungs being bound down to the ribs and intercostal spaces, have to be inflated and emptied by a sort of bellows process, performed by the sternum and abdominal muscles.

Mammalia.—It is unnecessary to do more, to make this account complete, than to give a bare outline of the respiratory apparatus in this class, inasmuch that of every member of it is pretty nearly identical with what is found in us. At the base of the tongue is the glottis, or opening into the larynx, protected by a valve, the epiglottis: the larynx, or broad cartilages of the trachea, is succeeded by the narrow cartilaginous rings of the trachea proper; this tube eventually bifurcates into the right and left bronchus, which ultimately split into numberless ramifications, and, losing their cartilaginous rings, terminate in membranous air-cells. Now, all the ramuli of the principal ramus, being bound up together by cellular tissue (the parenchymatous substance of the lung), divide the lung into lobes, whilst the ultimate subdivisions of the ramuli—the air-cells, being similarly bound up together, divide the lobe into lobules. The lungs are, moreover, lodged in a distinct cavity with the heart, formed by the development, in this class, of a muscular septum, the diaphragm. They are enveloped in a serous membrane, the pleura, which is reflected upon the walls, roof, and floor of their compartment, the utility of which is obvious. The muscular arrangements (considerably advanced by the addition of the diaphragm), for the accomplishment of inspiration and expiration, are likewise most complete.

The following table will perhaps convey some idea of the order of progression in the development of the important organ we have been considering:—

Classes.		RADIATA.
		Respiratory Organs.
Porifera	General surface, external and internal.	
Polypifera	General surface, external and internal.	
Acalephæ	Edge of mantle.	
Echinodermata ..	Peritoneum.	
		ARTICULATA.
Annelida	Surface, air-cells, cuticular branchial tufts.	
Insecta	General tracheæ.	
Arachnida	Pulmo-branchiæ.	
Crustacea	Branchial tufts, enclosed.	
		MOLLUSCA.
Tunicata	Peritoneum.	
Conchifera	Branchial frill, enclosed.	
Gastropoda	Pulmonary chamber, branchial frill, enclosed.	
Pteropoda	Surface of body.	
Cephalopoda	Branchial tufts, enclosed.	
		VERTEBRATA.
Pisces	Gills.	
Reptilia	Air-sacs.	
Aves	Subdivided lungs, respiratory cavity prolonged.	
Mammalia	Minutely subdivided perfect lung.	

For the length of time which has elapsed between the appearance of the first and second of these papers, I have illness to plead in apology. They shall, however, now continue, at short intervals, in an uninterrupted series. I would repeat the statement with which I concluded my former paper, namely, that, as this is an altogether elementary compilation, a very simple classification is adopted.

(To be continued.)

A STATISTIC AND CRITICAL REPORT OF THE EFFECTS OF ETHERIC INHALATION, FROM CASES RECORDED IN THE HOSPITALS OF PARIS.

Translated from the Original of Dr. BURGHIÈRES.

The action of ether on the lungs, by inhalation, establishes, beyond doubt, one of the most important events which the science of medicine has discovered for a long period. It is manifest that, by its nature as well as application, this event has attracted, and still attracts, the anxious attention of the public. After perusing the discussion which took place in the Académie des Sciences—after witnessing the most contradictory opinions maintained by men of eminence—

our readers should recollect, in the spirit of doubt, that the recitals of certain experiments made on dogs and rabbits, or the results of immersing in other portions of nerves separated from the body, are matters not for present consideration. It is only by observations made on the human body that we can determine the questions which have been raised. The reader will do well, from the great interest of our subject, to conquer his natural aversion to look on human misery, and follow us through our hospitals, where we call upon him to assist at those terrible operations, at those wonderful mutilations, which surgery is daily called upon to perform. He will now witness the wretched spectacle greatly divested of its horrors, for in most cases the patient, instead of relieving his anguish by heartrending cries, will remain calm and insensible, or, as occurs in some instances, will seem absorbed by some delicious ecstasy, at the very moment he would have suffered the most horrible tortures.

The question of suppressing pain during surgical operations is not of recent origin: several essays on this subject have appeared at different times; and the language used by surgeons previous to discovering the stupifying properties of ether is an object of curious consideration. Some idea may be formed from the following passage, extracted from the "Traité des Pathologie Externe," du M. Vidal (du Cassis):—

"*Suspension of Sensibility.*—It would be rendering a double service to the patient to suspend sensibility in that part which is to be operated on, in the same manner that we suspend the current of the blood, for pain is often one of the causes which makes us dread the operation. On the other hand, pain, when prolonged, causes to our organization a nervous loss (*perte nerveuse*) which is equivalent to a loss of blood. We may safely declare there are nervous losses as well as losses of blood."

Let us, however, abandon these theoretical pursuits and seek the field of observation. We shall here confine ourselves to facts which have been accomplished in our hospitals under the incontestable and valuable guarantees which publicity and science give to every transaction. Although the practice of etheric inhalation has been known in France for the brief period of two months, the number of trials is already sufficiently considerable to enable us to draw some important conclusions. We shall not advance these conclusions as definitive, but they may be considered, according to the expression of Bacon, as the first vintage (*premières vendanges*).

We shall divide into three classes the matters we are going to discuss in their order of relation:—1, as to surgical operations; 2, accouchements; 3, the employment of etheric inhalation as a therapeutic method of treating some diseases.

SURGICAL OPERATIONS PERFORMED UNDER THE INFLUENCE OF ETHER.

The number of operations performed under the influence of ether is already very considerable—a fact more attributable to the free will of the patients than a desire for experiment in the physicians and surgeons of our hospitals, who in this respect, whatever opinions may have spread elsewhere, have shown themselves very reserved. It is impossible to form a correct idea of the persevering determination with which patients in our hospitals beg to be etherized so soon as they perceive a surgeon refer to his instrument-case; and this is often done to escape the slight pain which might result from the simplest operation. Of two hundred and eleven operations, we are in possession of details sufficiently circumstantial to constitute the basis of an analytical investigation. The following list indicates the hospitals where these operations took place, and the surgeons by whom they were performed:—

HÔTEL DIEU.

M. Roux.

Amputation of the leg	1
Amputation of the thigh	1
Amputation of the fingers	3

Brought forward	6
Tumour of the breast	1
Tumour of the face	1
Extraction of oruosis (qy. J. E. W.)	1
Fistula lachrymalis	1
Fistula in ano	2
Phimosis	1
Incisions, excisions, &c.	30 — 42
M. Blandin.	
Amputation of bone of the foot	1
Amputation of bone of the breast	3
Fistula in ano	3
Actual cautery	5 — 10
M. Boyer.	
Amputation of the limb	1
Amputation of the finger	1
Extraction of the nail	1
Moxas	1 — 4

HÔPITAL DE LA CHARITÉ.

M. Velpeau.

Amputation of the leg	1
Amputation of the breast	1
Sarcocoele	1
Partial amputation of the foot	1
Removal of cancerous tumour from the thigh	1
Removal of cancerous tumour from the parotid	1
Removal of cancerous tumour from the eye	1
Partial amputation of the hand	1
Fistula in ano	2
Excision of the glands of the throat	1
Abscess of the breast	2
Removal of the nail	1
Reducing a luxation of the hip	1
Reducing a luxation of the elbow	1
Reducing a fracture of the thigh	1
Iodine injection into the articulation of the knee	1 — 18

M. Gerdy.

Cataract	1
Amputation of forearm	1
Removing polypus from the nose	1
Seton	1
Reducing hernia	1
Incisions, excisions, &c.	4 — 9

HÔPITAL DE ST. LOUIS.

M. Jobert (de Lamballe).

Amputation of the thigh	1
Amputation of the leg	1
Amputation of the arm	2
Tumour of the breast	2
Tumours various	3
Fistula and fissure in ano	2
Actual cautery	2
Luxation of shoulder	1
Hydrocele	1
Incisions, excisions, &c.	20 — 35

M. Malgaigne.

Amputation of leg	4
Removal of tumours	2
Amputations of fingers and toes	4
Incisions, excisions, &c.	10 — 20

HÔPITAL BEAUJON.

M. Langier.

Amputation of thigh	3
Amputation of leg	1
Excision of tumours	1
Strangulated hernia	1
Moxas	1 — 7

M. Robert.

Amputation of leg	1
Section of tendo Achilles	1
Reducing dislocated elbow	1 — 3

M. Bouvier.

Section of tendo Achilles	1
Strabismus	1 — 2

HÔPITAL DE LA PITIÉ.

M. Giraldes.

Amputation of thigh	1
Amputation of large toe	2
Removal of tumour	1
Hydrocele	1
Ongles incarnés (qy. J.E.W.)	1
Incisions	2
Actual cautery	1 — 9

Brought forward 195

MAISON ROYALE DE SANTÉ.

M. Monod.

Amputation of finger	1
Amputation of breast	1
Circumcision	1 — 3

HÔPITAL DU BON SECOURS.

M. Denonvilliers.

Amputation of fingers	2
Incisions, excisions, &c.	18 — 20

HÔPITAL DES CLINIQUES.

M. Voilemier.

Amputation of the leg	1
Amputation of the arm	1
Removal of lipomas volumineux (qy. superabundant fat, J. E. W.)	2
Removal of tumour encystous	1
Removal of a needle	1
Removal of polypus of the nose	2
Division multiple d'un varte enthrax (qy. J. E. W.)	1
Removal of nail	1 — 10

HÔPITAL COCHIN.

M. Michen.

Lithotrixy	1
Amputation of toe	1 — 2

HÔPITAL DES ENFANS MALADES.

M. Paul Quersant.

Operation of the taille (qy. J. E. W.)	1
Amputation of thigh	1
Amputation of arm	1
Amputation of fingers and toes	5
Fistula in ano	1
Actual cautery	1 — 10

HÔPITAL DU MIDI.

M. Vidal (de Cassis).

Varicocoele	2
Phimosis	1
Strabismus	1 — 4

208

Before we enter upon a detail of particular facts, it will be necessary to establish certain generalities, emanating from experience acquired in relation to the construction of apparatus, to the choice of ether, to the preparation of the patients, and to the effect of etheric inhalation.

Construction of the Apparatus.—It is highly important to the success of etheric inhalations to use good apparatus; and we must, without doubt, attribute to the imperfect construction of those hitherto employed certain negative results which obtained on the first attempts. The apparatus which is now used in our hospitals, and for which we are indebted to Messrs. Luer and Charrière, furnishes, to a degree approaching to perfection, every essential requisite.

The ether is to be secured in a pint bottle (litre), because at each inspiration there enters naturally to the lungs from half a pint to a pint of air. The conducting tube ought to be, at least, equal in its diameter to the tracheal artery. The etheric vapour should be conveyed to the respiratory organs only by degrees; this is to be accomplished by an ingenious arrangement of the cyphon which closes the bottle, so that, according to the turn or position of the cyphon, the proportion of etheric vapour is augmented, until, the valve being completely opened, the patient inhales exclusively the air which is saturated with ether.

The patient is brought in contact with the apparatus by means of an *embouchoir*, which, by its construction, adapts itself precisely to the form of the mouth. The nostrils ought in this case to be kept closed, either by the fingers, or by springs prepared for the purpose. M. Cloquet has a contrivance which adapts itself to the nasal orifices: in this case the mouth should be kept shut. In conclusion, a valve situated near the mouthpiece prevents the breath given out from returning into the apparatus.

Choice of Ether.—Although many preparations of ether possess the power of stupefaction, the hydic called sulphuric ether is that which is to be preferred. It should be as pure as possible—the more it is pure the more it is volatile, and

produces its effects with promptitude and success. It is also very essential to separate from it completely all sulphuric acid, of which it sometimes contains certain particles—a consequence resulting from the method by which it is prepared (distillation of a mixture of alcohol and sulphuric acid). According to certain discoveries made in England, the irritation which has attacked the respiratory organs, in certain cases of etheric inhalation, is attributed to this mixture of sulphuric acid. Ether perfectly pure will not produce these accidents; indeed, we should be careful to renew the ether upon every experiment, for by its evaporation it loses its most volatile and active particles. We have more than once seen the effects delayed for a long time, or entirely fail, because this precaution had been neglected.

Preparation of the Patients.—Many surgeons, particularly Professors Roux and Velpeau, subject those patients which are to undergo important operations to a preparatory process of etherization. We shall presently see the advantages, in some cases, of knowing beforehand the susceptibility of the patient, and the peculiar influence of the ether on his constitutional character. It is almost always necessary to the success of etheric inhalation that the patient should be taught to breathe through the inhaling apparatus. There are some who readily adapt themselves to its uses on the first trial. When, therefore, the patient is accustomed to breathe the pure air through the mouthpiece, the cyphon should be gradually turned so as to mix the etheric vapours by a gradual increase with the air which he inspires. It will also be found useful, as regards the compression of the nasal orifices, to follow the example of M. Jobert: this surgeon abstains, with reason, from employing the pincers which are manufactured for this purpose; he allows the nostrils to remain open during the first period of the etheric inspiration, and then closes and relaxes them alternately several hours in succession, to avoid definitively collapsing them until the inhalations have acquired a regular character.

Effects of the Ether.—Although the application of ether to the lungs is a recent discovery, we may assert that physiology might have foreseen it. A substance eminently volatile is brought in contact with a very extended surface of the mucous membrane, endowed with a very positive absorbent faculty, and situated close to the fountain of circulation. The ether, therefore, is immediately carried into the blood and produces a specific action on the nervous system (*centres nerveux* J. E. W.). We shall divide, in conformity with the doctrines of MM. Jobert and Blandin, the successive phenomena of etherization into three periods:—

First Period.—In the first instance the ether produces on the mucous membrane of the bronchia an irritation which is accompanied by a sense of pricking and heat; this is shortly succeeded by a very agreeable and refreshing sensation. The cough, which is provoked in most cases by the first etheric inspirations, soon subsides, but the breathing remains quick and irregular for some time; the circulation quickens, and the pulse increases from 100 to 120 per minute. On the nervous system the phenomena produced by the first effects of the vapour are those of excitement: the patient is agitated, his voice short, and his ideas, in most instances, wander; he exhibits signs, sometimes of gaiety, then of ill humour, and not unfrequently of rage; sensation is also sometimes rendered very keen at this period, and the slightest touch becomes painful.

Second Period.—To the phenomena of excitement shortly succeed the effects of stupefaction. The disordered movements subside into calm, and the muscles become relaxed; nothing is now perceptible but a slight tremulous action of the eyelids, entirely characteristic. The mind is weakened, perception ceases, the senses become obtuse, the patient abandons all communication with the external world, he is motionless, and appears plunged into profound sleep. If we appeal to his sensitive faculties he feels, but he is no longer conscious of what is done to him.

According to the experiments of MM. Flourens and Louget this period corresponds with that of the etherization of the lobes of the brain, and the "ecrêpe": these organs which preside over the phenomena of intellect and the co-ordination of motion. The respiration is now calm, and the pulse restored to its normal character.

Third Period.—The third period is essentially characterized by a diminution or total suspension of sensibility: this faculty is extinguished by degrees, when at length we may pinch, prick, and even burn the skin of the patient without his manifesting the slightest consciousness. This is the time usually chosen to perform the operation—the moment which is termed the "surgical period." There exists at this time, according to physiological theory, etherization of that portion of the principal nerves which has received the name of the auricular protuberance.

If the etheric inhalation is now prolonged for any time the etherization is carried to the *bulbe rachidien*, the principal seat of respiratory motion—the source even of life itself. The breathing is rendered embarrassed—it becomes slow and stertorous, the circulation is fettered; the pulse becomes slow, small, and irregular; the extremities chill and turn purple; asphyxia is imminent. It is in this state that animals die on whom the etheric inhalation has been practised, and we may readily comprehend the valuable caution which the surgeon ought to acquire by these experiments. He should never forget that the ether which extinguishes pain may arrest life.

Such are, in most cases, the successive and progressive phenomena attendant on the inhalation of ether. The general account we have given carries with it more than one objection; and thus it is correctly observed by M. Malgaigne: "It is with ether as with wine—the intoxication it produces is of endless variety. Cheerful or sad, loquacious or taciturn, gentle or furious, &c., according to the individual."

Amidst these varieties there are some which, however great their physiological interest or their rational importance, deserve our most special consideration, in consequence of the operation to which the patient is submitted. We shall now proceed to direct our particular study to some of them, and thus we shall be enabled by the facts which we possess to determine, by means of observation, many of the disputed questions which relate to the employment of etheric inhalations in the practice of surgical operations.

(Signed) LE DR. BURQUIERES.

(To be continued.)

FURTHER REMARKS ON DISSECTION WOUNDS.

By J. E. PATTISON, Esq., M.R.C.S., Islington, London.

(Continued from p. 116.)

In my last paper I endeavoured to prove the similarity of symptoms arising occasionally from simple wounds to those observable in dissection wounds. In my present communication of cases it will be seen that the fatal termination of one of them, and the dangerous array of symptoms of others, cannot be explained on what Mr. Lawrence terms being "out of health" at the time of receiving the wound or infection; inasmuch as the subjects of these cases were, at the period of making the *post-mortem*, in the full tide of health and enjoyment. In proving by these cases the influence of a septic agent, I ought, perhaps, to do so with some deference to those high authorities who attribute the malignity of the symptoms to the bad state of health of the recipient of the dissecting wound; yet, on reading over their reasoning or argument, it appears to me that they have very little confidence in their own judgment. Take for instance Mr. Lawrence's notice of Dissection Wounds, as published in the *Medical Gazette*. In the first part of the lecture he speaks thus:—"It appears to me very doubtful in this case (speaking of dissection wound) whether anything that

can be called virulent or poisonous is introduced into the human frame by these occurrences, or whether the effects are to be explained as resulting from such injuries considered mechanically;" and then, after a weak attempt to prove his case, in a subsequent part of the lecture, he, as though conscious of the weakness of his argument, confesses, "it is perhaps rather a question of curiosity than one of direct practical consequence, whether these effects arise from a poisonous matter communicated to the part, or whether they owe their origin to the particular state of the individual at the time the wound is inflicted."

On looking more minutely into the subject, the question resolves itself into the probability or possibility of animal substances in certain states of decomposition becoming active poisons when applied to the living structures of even healthy subjects; and I think few who dispassionately examine the record of melancholy cases handed down to us in the journals, as seen to occur from dissecting in the public dissection-rooms amongst our students, whose health, perhaps, from study and half-and-half, may likely, especially towards the fagend of a session, be below *par*—as is seen also in too many mournful cases amongst the worthy class of general practitioners who minister to the sick in our rural districts—few, I expect, are there, who will examine the question fairly, but must own the influence of a septic agent in a certain proportion of the cases as yet recorded. The two instances I have to notice are cases that occurred in country practice, and tend clearly, in my own mind, to prove the agency of a morbid poison, as the subjects of them were, in every sense of the word, in robust health, living in pure air, taking plenty of exercise, were free from any specific hereditary disease; were both young, strong, and active, and had no anxieties or fretful cares to interfere with the healthful tone of their existence.

I shall first describe the symptoms in my own case.

I, when a pupil, had been attending a poor young woman, the wife of a manganese miner, for gastritis; the symptoms were severe pain and heat in the region of the stomach, violent and painful vomiting, great prostration of strength, small and rapid pulse, pain increased by pressure, the fauces were peculiarly red, and the tongue glazed and parched. From the urgency and severity of the symptoms it was manifest from the first that not only all the coats of the stomach were affected, but that the peritoneum also partook of the disease. The patient, who was far gone in her gestation, died rather suddenly, and, it having been observed by the neighbours that her husband and herself at times quarrelled, a very meddlesome magistrate, extremely ignorant of everything about the case, and without even consulting the medical practitioners in attendance, peremptorily ordered a *post-mortem* examination and coroner's inquest. So, notwithstanding her death was clearly owing to natural disease, yet it was required of us to institute a searching inquiry, to make a minute *post-mortem* examination, to analyse the contents of the stomach, &c.

It was winter when these occurrences took place, and early in the morning the junior partner of the firm, Mr. Patch, a truly worthy member of the profession—young, generous, and enthusiastic in all that related to medical and surgical science, and in private life, honoured and respected by all who knew him—accompanied by Mr. Alfred Collinson, now in practice at New Cross, Dr. John Scofield, now in London, and myself, to the room where the dead lay for our inspection, ere it was placed in the coffin. Mr. Patch, a young enthusiast in his profession as he was, said he was glad of the occurrence for one thing, namely, that the subject would afford an excellent demonstration to us of the *fortus in viro*. So, as soon as he had tied each opening of the stomach, in order to secure the contents for analysis, and had separated it for taking home, he began his demonstration of the gravid uterus, and in doing so, naturally handled much the intestines and peritoneum, and by some means,

slightly, very slightly, scratched his finger, which he had no sooner done than he sucked the part, and continued his demonstration as though nothing had happened. Before sewing up the body, I handled the intestines in learning the divisional boundaries of each section of the canal; and, having an abraded spot on one of my fingers, was liable also to inhale the infection. Mr. Collinson also had either an abraded finger, or pricked himself, I know not which, hence he was exposed to the infection as well, and suffered severely. Dr. Scofield escaped, he having handled the parts but little, merely to the extent of putting the contents of the stomach into a flask for analysis.

On returning home we felt nothing immediately, but in a short time all who were engaged in the *post-mortem* became more or less affected with peculiar states of feeling, and symptoms ushering in an abnormal condition of the body. The first decided symptoms I experienced were a peculiar depression of my wonted energy or activity. I felt low and melancholy, experienced a disposition to scream, was shivered, and had nausea; after a little while, in the course of the afternoon, my head ached severely, and I vomited freely; my pulse was sharp, quick, and weak; tongue dry. The local symptoms were scarcely observable at first; the nail-spring looked a little red, and the corresponding shoulder-joint was painful; in a few hours it became more so, and the axilla was puffed. The skin over the pectoral muscle assumed at first a pale tinge, and shortly afterwards an erysipelatous peach-blossom hue characterized its surface. In this stage of the symptoms the difficulty of breathing set in, which was peculiarly distressing; the tongue became tremulous, and had a brown or incipient typhoid character, as the case progressed; the lowness of spirits increased, and the mental distress (so generally seen in dissection-wound cases) was very apparent; the expression of the countenance was haggard in the extreme, and the complexion yellow and cadaverous-looking. In a short time all these symptoms increased in severity, others also of an alarming nature followed: delirium set in, the prostration of strength became extreme, the sphincter lost its power, and the feeling of suffocation threatened speedy destruction.

It was at this period of the attack, when everything seemed to point to a fatal termination, that, on a particular examination of the chest being instituted, Dr. Anderson—called in for consultation—proposed incision through the pectoral muscle, to free any matter that might have formed, for as yet no distinct fluctuation could be felt. On making a free incision, a very large quantity of pus and blood was discharged, which instantly, to some extent, relieved the feeling of suffocation that threatened to destroy life a few minutes before; the discharge continued so profuse that it became necessary for me to take large quantities of wine and nutritious diet, to support the system; subsequently to this, the constitutional symptoms slowly abated, and in a few weeks, after a visit to Rensselaer for change of air, I was perfectly recovered.

The treatment adopted was general bleeding from the arm at the onset of the disease, followed by mercurials till the mouth was slightly affected. Morphine was given at night to procure sleep, and the local affection of the pectoral muscle constantly fomented to encourage the formation of matter.

In the other case that I have to notice, that of Mr. Patch, which terminated fatally, it will be unnecessary to detail the whole of the symptoms, as they, in almost every particular, resembled those that occurred to me; the treatment was, however, opposite to that which it was thought proper to put me under. Mr. Patch prescribed for himself; I, being a junior, and but a tyro in the profession, did not presume to do so. I was bled, mercurialized, and incised, after the old fashion of *medicinae ars conjecturalis*, whilst my fellow-sufferer would neither allow himself to be bled, mercurialized, nor have his pectoral muscle

meddled with till too late, so that nature, in the powers of his constitution, which was remarkably vigorous and active, had fair play to combat the disease. For some days he had the advantage over me in respect to the severity of the symptoms, and every one thought he had a better chance of recovery; still this hope was but illusory, as his symptoms took a sudden change for the worse, and he rather unexpectedly died, adding another to the melancholy list of deaths from dissection wound.

Remarks.—These two cases, though but imperfectly reported, cannot fail of proving the antiphlogistic plan of treatment to be the correct one in the ordinary management of wounds received in *post-mortem* examinations. On comparing the symptoms, as developed in Mr. Patch's case, with my own, the comparison would, if anything, be in his favour; and as regards our general health and habits of body, I must notice that his temperament was well-marked lymphatic, whilst mine was sanguineous; and that therefore, those who argue, as some do, for the distinctive type of this disease to consist of inflammation of the lymphatics, will likely trace the cause of his death to have been dependent on his temperament. However this may be we know not, yet I truly believe that had he suffered himself to have been freely bled at the onset of the attack, and had there been a free incision made into his pectoral muscle, and had he undergone a course of mercurial medicines, his life would have been preserved: for the disease is essentially one of inflammation, though of a peculiar type, attacking in some instances the cellular structures, in others the lymphatics and glandular.

As regards the doctrine of introduction of a morbid poison, I think the evidence goes very far to prove the correctness of that view, as the other parties who attended at the *post-mortem*, but who received no direct inoculation, were affected either through the skin or lungs, and suffered, though in a comparatively mild form, many of the symptoms of the same disease.

With respect to the fact of anatomists, many of them having been free from the disease all their lives, though in the habit of constantly dissecting and making *post-mortems*, it may be explained first of all on the well-known fact that the subjects for the dissecting-rooms are very far from being recent subjects, and that putrefaction or decomposition tends, every day after death, to neutralize even the poison of the worst cases of peritoneal inflammation; and secondly, their immunity may in many cases be explained on the principles or laws of predisposition, which, however mysterious to us, are known to free certain constitutions from the ill effects of malaria, and other poisons equally as baneful as the septic of the recently dead.

Some have disputed the agency of a septic agent on account of the variety of effects to which it gives rise; thus, in the *post-mortem* that was the cause of Mr. Patch's death, of the surgeon and pupils engaged, it caused death in one, serious and dangerous disease in another, great disturbance in the general health of the third, whilst the fourth experienced but slight effects from it. It is possible that these different effects may have been the result of different poisons absorbed even from the same subject, or of different portions or doses of the virus introduced, or they may be the result of the same morbid agent, modified by the different constitutions or temperaments of the several individuals; yet I think, whatever explanation we adopt, we must attribute the symptoms in each case to septic absorption.

A NEW MODE OF TREATING UTERINE HEMORRHAGE.

By T. B. TORRUCK, M.D.

(Continued from p. 175.)

CASE VI.—This case was reported by my friend Mr. H. H. Taylor, surgeon, of Sunderland, and at first supposed to be one of hemorrhagia on account of age, more especially the female not having conceived for several years. However,

it was subsequently discovered that an ovum had been thrown off. Mary Reed, aged forty-six years, mother of a large family, leucæ-phlegmatic temperament, with a redundancy of fat, tissues loose and flabby, was seized on the 30th of September, 1846, with considerable discharge of blood from vagina, but for several days did not consult her medical attendant. The discharge continuing unabated, created great alarm, when Mr. Taylor was sent for, who, on his arrival, inquired strictly into the symptoms, and moreover found a considerable quantity of coagula had been thrown off. The patient at this moment being free from pain, he was not led to institute an examination *per vaginam*, but prescribed tannin, acetate of lead combined with opium, secale, &c. sold appliances, support in the form of external compression to the uterus, &c.; notwithstanding, the hemorrhage continued unabated, when I was requested by my friend in consultation. On examination it was found an ovum had been thrown off, the mouth of the uterus scarcely admitting the finger; we at once decided on injecting the uterus, notwithstanding there was considerable difficulty in introducing the uterine tube; this being accomplished, four ounces of brandy were injected, when the hemorrhage ceased; no untoward symptom followed, and the patient gradually recovered.

CASE VII.—The following cases are also reported by Mr. Taylor:—Mrs. N., aged twenty-six years, of a spare delicate habit, the mother of one child, was seized with labour on the 30th of October, 1846. Nothing of importance occurred until after the birth of the child, when it would appear she became suddenly faint, which was discovered by her medical attendant to arise from loss of blood. The placenta had not then been expelled, neither was there a disposition to uterine contraction. In the interim the several remedies were employed, notwithstanding the hemorrhage continued unabated. Manual efforts were now had recourse to, so as to remove the placenta, when the uterus was found to resemble a distended bladder filled with coagula. This was removed, and a sponge perfectly saturated with brandy-and-water conveyed into the uterus, when contraction immediately took place. A second attempt was made by my friend to introduce the sponge, who found the contraction so complete as to oblige him to desist. This patient recovered rapidly, without the least untoward symptom following.

CASE VIII.—Margaret Emmerson, between the age of twenty and thirty years, was taken with labour September 20, 1846. On examination, was found to be progressing favourably; during the absence of the medical attendant for a few minutes, in an adjoining apartment, she was suddenly seized with violent heaving-down efforts, which caused the expulsion of the child upon the floor; the umbilical cord ruptured—(this arose from the patient rising from her bed, notwithstanding the remonstrances of her medical attendant)—she was at once conveyed to her bed, when, after the lapse of from fifteen to twenty minutes she exclaimed, she was dying. On examination it was found that a great loss of blood had been sustained in the meantime, there now existing a passive state of the uterus. Pressure, cold appliances, secale, stimulants, &c. Three doses of secale had now been given, amounting to two drachms, still no contraction of the uterus. Rum, with water one-third, was now injected into the uterus, when speedily the uterus contracted and the placenta was discharged, and the hemorrhage arrested completely. This case bears a strict analogy to the one recorded by Dr. Clancy, which proves more particularly in this case the necessity, when the uterus is in an atonic state, of throwing stimulants into its cavity, so as to induce contraction, rather than resorting to manual efforts to remove the placenta.

Kirkby Stephen, April 17.

OBITUARY.—On the 18th inst., at his residence in Harley-street, William MacLure, Esq., surgeon, aged 66.

PARALYSIS IN THE BRANCHES OF THE FIFTH PAIR OF NERVES ON THE RIGHT SIDE OF THE FACE.

By J. F. MARTIN, Esq., Highworth, Wilts.

HISTORY.—T. W., thirty-four years of age, of good health and sound constitution till the present time, attributes his ailment to a pugilistic encounter, wherein he received a blow on the crown of his head, about thirteen months since, subsequently to which, headache and difficulty of lowering the brow was experienced, particularly on the right side. In a fortnight a singular sensation came on in the right ear, which he compared to the sound of bellows blowing softly; the same phenomenon had appeared for the first time, a few days after the injury, but now it was constant; he had never suffered in his power of hearing. On the 14th of January last he perceived his right cheek swollen, his mouth drawn aside, speech much affected—ailments which increased for a few days. On the 20th he could scarcely close his right eye; the sight of which was impaired; he had no sense of taste remaining on the right side of his tongue, and he heard less perfectly with his right ear.

PRESENT SYMPTOMS.—On the 15th of February I was requested to visit him, and found, upon examination, his mouth drawn on the left side; his right brow cannot be lowered, or his left eye closed, the orbicularis palpebrarum being paralysed; the right side of his mouth is void of sensation, excepting near the junction of the lips; over the right side of the tongue, taste is lost throughout that side; he can move his tongue in all directions with freedom; he cannot distinguish acids on the right side of his tongue, which was tried to ascertain its sensibility; a probe introduced into the external passage of the right ear was not felt, though very disagreeable when introduced into the left ear; the same differences were observed between the left and right nostril; the sense of smell is quite gone from the right side. A feather drawn along the left side of the mouth was disagreeably felt, but not on the right. The conjunctive membrane was equally sensitive in both eyes, and he could swallow easily. For the last few days he felt pain over the left parietal protuberance, and over the left eyebrow, whenever he coughed; in everything else he was in perfect health; sensation was lost all over the right side of the neck.

TREATMENT.—A dozen leeches applied over each mastoid process, and cataplasms of mustard to the lower extremities. 3jss. infusion of senna with manna every six hours, and low diet. On the 16th the disfigurement of the mouth was less, and his headache better; slight sensation on the right side of the tongue at its base, and over the right side of the face and mouth: to continue the infusion of senna, &c., three times a day, and apply the compound camphor liniment by way of friction behind the ears. On the 17th the right eye could be closed, but taste had not returned to the right side of the tongue or palate; the pupils were in a normal condition, and he could read easily, though previously he had seen but imperfectly on closing the left eye; can hear better, but the bellows sound continues. By the 23rd, sensibility was wholly restored; the right eye can be readily closed, and the brow can be moved with little difficulty; the mouth is still a little aside; but from this time the case rapidly improved, and he is now quite well.

PROGRESS OF MEDICAL SCIENCE.

France.

ACADEMY OF MEDICINE.

Meeting of April 20; M. BROIN in the Chair.

TYPHOID FEVER.

A communication was read from Dr. Leurat, of Lyons, on the efficacy of the "sirop de co-

déine," in the treatment of the ataxic form of typhoid fever.

M. Louis supposed that it was of narcotics in general that the author intended to speak: and the advantages which followed their exhibition in fever were now well known, and admitted on all hands.

M. Dubois remarked that M. Leurat precisely established a distinction between preparations of opium and codéine; to the latter substance he attributed particular virtues.

M. Martin Solon observed that five years since a commission had been named by the Academy for the purpose of examining the various theories adopted on the subject of typhoid fever, and also the various treatments recommended by different practitioners. Illness had prevented the reporter of that commission from presenting to the Academy the result of its researches, but he hoped in a few weeks to be enabled to do so.

M. Ferrus had lately witnessed in a prison of one of the northern provinces of France an epidemic of typhoid fever, which raged more particularly upon male subjects, affecting at first a mild form, but afterwards assuming more serious characters, and presenting symptoms of an epileptiform appearance. In several patients absorption of the fluids of the eye was noticed, and vision was abolished. The epidemic was attributed to the crowded state of the establishment. *Post-mortem* examinations did not invariably show the presence of ulceration of Peyer's glands, and opium had been the most successful of the remedies resorted to.

M. Louis was of opinion that it would be wrong to conclude from M. Ferrus's statements that the ulceration of Peyer's glands was not intimately connected with typhoid fever. For his part, M. Louis had always noticed the coincidence. In Gibraltar M. Louis had seen cases of yellow fever which might have been confounded with instances of typhus; but, whenever he had found after death the anatomical characters of yellow fever, the symptoms of that malady had invariably existed during life.

The meeting adjourned at an early hour.

The meetings of the Academy of Sciences have offered of late but little interest in a medical point of view. At the meeting of April 19, however, a person with whom we were in hopes to have done—M. Ducros, who, it may be recollected claimed, "for the honour of France," the credit of the Jacksonian discovery—again put in his claims but to another and more ancient invention: it is the reflex action of the spinal chord which M. Ducros's researches now give to the world; in fact, in making the discovery fifteen years too early, Marshall Hall has done M. Ducros an injury of a serious nature. A short debate ensued after this communication, in which we were somewhat surprised to hear M. Magendie state that reflex action of the spinal chord depended solely upon cerebral influence. We must acknowledge we had hitherto been under the impression that it had been demonstrated to exist in decapitated animals, and in extremities paralysed in consequence of cerebral hemorrhage. M. Baudiloeque reported a case of cure of deafness in an infant, by perforation of the tympanum with a special catheter of his own invention.

THERAPEUTIC AGENCY OF NITRATE OF POTASS.

—The exhibition of this salt in large doses is a practice of no very recent date: in hemorrhage, Stoll, Dickson, and Gibbons have recommended its use; and in hemoptysis, Laenne has employed it with advantage; in rheumatism and inflammatory fever, M'Bride, Robt. White, Brocklesby, and, more recently, Gendrin and Martin Solon have proved its efficacy. Dr. Mazade, encouraged by their success, has exhibited this medicine in large doses, in that form of dropsy occasioned by or attended with febrile excitement, and records the results of his researches in the *Bulletin de Thérapeutique*; four cases of dropsy are published in the article referred to. The first was one of ascites, consequent upon intermittent fever and

enlargement of the spleen. Each day the patient took from 3 iij. to 3ss. of nitrate of potass in a quart of fluid; and the effusion was dispelled in a few days. The second case refers to a woman who became affected with anasarca and ascites, in consequence of the sudden suppression of the catamenial secretion. The same doses were exhibited, and on the eighteenth day the dropsy had disappeared. A stonemason, after prolonged exposure, was seized with fever, during which anasarca and dropsy manifested themselves; they had lasted twelve days, when the treatment with nitrate of potass was instituted, the dose was carried from twelve to twenty grammes, and in the space of ten days health was restored. The fourth case refers to an aged lady, who was labouring under symptoms of organic disease of the heart; the infiltration and ascites had become so abundant as to cause much distress, and even feverishness. Nitrate of potass was exhibited in doses, gradually increasing from 3 ij. to 3ss., and in one fortnight the serous effusions were absorbed. The same result was again obtained twelve months later in the same patient, who finally died from the progress of the disease of the heart. In these cases, the first effect of the medicine appears to have been a considerable increase of the renal secretion; and the second, a diminution of the frequency of the pulse. There remains little doubt but that in all these cases a similar result might have followed the adoption of other anti-phlogistic remedies, but still this method may, in our opinion, be often called upon to render most valuable assistance.

HOOPING-COUGH.—Professor Trousseau recommends the following solution of nitrate of silver in cases of whooping-cough:—℞. Aq. distil., 3j; syrup. simplicis, 3ss.; argenti nitratis, gr. one-fifth: to be taken daily.—*Bulletin de Thérapeutique*.

HÔPITAL SAINT LOUIS.

Spontaneous Gangrene.—A painter, aged thirty-nine, was admitted for this malady into the wards of M. Jobert. Since seven years, pains had appeared in the left leg and foot; their character was erratic at first, but their intensity gradually increased, and now since three years they had become continuous. Six weeks ago the foot had grown black, and numerous phlyctenæ had made their appearance. The skin of the toes was dark and corrugated; on the back of the foot the gangrene seemed to be more of a humid nature; a broad greyish eschar occupied the front of the tibio-tarsal articulation; and at a very short distance higher up, a well-limited redness, which had remained stationary for some days, seemed to indicate that the local damage had ceased to progress. The patient was therefore brought to the operating-theatre and placed under the influence of ether; in the space of four minutes unconsciousness was produced. The limb was amputated at its lower third, and union by suture attempted. During the first days which followed the operation fever was continuous, delirium appeared, great prostration, and finally gangrene of the sacrum and of the soft parts of the stump. Twelve days after amputation the patient died. On dissection of the foot the tibial arteries were found obliterated.

PROCEEDINGS AT NICE.

The political papers (the *Presse* and *La Patrie*, April 24) furnish a garbled and partially false account of the following transactions, which we think it our duty to place in their true light before the British public:—

On the 16th of January, Dr. Gurney, of Nice, was for the first time called upon to attend Miss S., aged twenty-four, of a sanguine temperament, and who, three years previously, had laboured under symptoms of a doubtful nature, which Dr. Gurney did not hesitate to attribute to trismus. When that gentleman first saw his patient she appeared to him to be suffering from torpor of the liver. A gentle mercurial and saline draught were recommended, and amendment ensued. A relapse having occurred, the same medicines were exhibited, but the same improvement was

not obtained. On the 20th continual vomiting appeared; the tongue was coated, the abdomen tender in the right hypochondrium, and the pulse at 80. Effervescing draughts were prescribed, and at the same time the following mixture:—*R. Sodæ sesquicarb.* 3j.; *acid. hydrocyan. gutt.* viij.; *muriatis morphiæ*, gr. j.; *syrup. amant.*, 3 viij.; *aquæ puræ*, q.s.; *ut fiat mist.* ʒvj. = *R. Pulv. acid. citrici*, gr. xl.; *f. pulv.* vj. Poultices were applied to the abdomen; no relief whatever was obtained; a bilious evacuation took place from the bowels. The pulse rose to 112; eighteen leeches were applied to the abdomen; an enema, containing ninety-five drops of laudanum was thrown up into the intestine, and the patient placed in a bath, which seemed to afford some relief. The spasms continued, collapse showed itself, and the patient expired at half-past two p.m., on the 22d of January.

In all, the patient had taken twenty drops of the hydrocyanic acid of the French codex, and two grains and a half of muriate of morphia. The stomach constantly rejected each dose immediately upon ingestion, with the exception of one. Six bottles of soda-water were exhibited, and when the patient died the pupils were in a state of dilatation—a circumstance carefully to be noted, inasmuch as it was asserted that death had been the result of poisoning by morphia.

Dissection of the Body six hours after Death.—Countenance natural; skin healthy; pleura free from adhesions; air-cells of central parts of lung unusually distended; heart of physiological size but more flaccid than ordinary. The stomach contained about two ounces of bilious fluid, that viscous being free from all appearance of inflammation or disease of any kind; the liver large, especially the right lobe; gall-bladder distended with inspissated bile—its duct, at four lines from the bladder, contained a small, fatty, highly vascular morbid growth; the intestinal mucous membrane natural; the peritoneum healthy, with the exception of a portion over the small intestines, where the vessels were much injected, but without thickening or adhesion; no intussusception or strangulation of intestines; the bladder healthy. The minutes of the *post-mortem* examination were signed by Mr. Farr and Henry C. Guiney, M.D. and dated Nizza, January 22.

Nice being a gossiping place, many idle rumours were circulated. It was stated by some that Miss S. had died in a cold bath; by others, that she had been the victim of guilty negligence; by a third set, that a Russian lady had caused her, by jealousy, to be poisoned, and that Dr. Gurney had received 30,000 francs for the purpose. It was even said that Miss S.'s body had been opened before life was extinct. In consequence of these rumours Dr. Gurney was, on the 26th of January, arrested, and retained three days in the company of common felons. A surgeon was at the same time appointed by the civil powers to examine the body; he did so, and stated to her British Majesty's Consul at Nice that he had detected no signs whatever of poison.

Dr. Gurney having complained to the English Minister at the Court of Turin of his treatment, the following letter was received from Lord Palmerston in explanation:—

"Foreign-office, February 21, 1847. (Copy.) Sir,—I am directed by Viscount Palmerston to inform you that a despatch has been received from her British Majesty's Minister at the Court of Turin, enclosing the correspondence between himself and the Sardinian Minister for Foreign Affairs, on the subject of the arrest of Dr. Gurney at Nice. From these documents it appears that the arrest of Dr. Gurney was the consequence of an infraction, unintentional, indeed, on his part, of the existing laws of Sardinia, he having proceeded without proper authority to make a *post-mortem* examination of the body of Miss S. six hours after death; that there was nothing in the subsequent proceedings tending to show any desire on the part of the Sardinian authorities to press harshly on Dr. Gurney; and that those authorities, having convinced themselves that there was no ground for the suspicion

of improper treatment, or for attributing to that gentleman any wilful intention to violate the laws by the hasty and unauthorized examination he had made, had acquitted him free of all costs. Viscount Palmerston entertains no doubt that these circumstances will dispel from the mind of the public at Nice all impressions which could in any way be prejudicial to Dr. Gurney's personal or professional character; and he therefore trusts that the above explanations will prove satisfactory to you.—I am, Sir, &c.,

(Signed) "E. G. STANLEY.

"To Rev. T. Gurney." Examining these transactions in a scientific point of view, we may first inquire, what did Miss S. die of? The diagnosis of Dr. Gurney was "a gallstone impacted in the duct," and the presence of the small fatty tumour in that position seems to support the correctness of this diagnosis. The absence of real icterus leads us, however, to doubt that this was the true and only cause of the symptoms, and of their fatal termination. With regard to the treatment, we may say that Miss S. did not die with the symptoms of narcotism, and, therefore, not from the muriate of morphia; as to the hydrocyanic acid, that is a more delicate question. The hydrocyanic acid of the London Pharmacopœia contains, we believe, two per cent. of the anhydrous acid; the hydrocyanic acid of the French codex contains, we are certain, 15 per cent. of the same anhydrous acid; twenty drops of the latter, the dose exhibited in eighteen hours, was, therefore, a quantity more considerable than Dr. Gurney had any intention of exhibiting. The effects of prussic acid on the system are, however, of a sudden, not a cumulative, nature; its evaporation is extremely rapid, and prevents a second dose, given a few hours after a first, from increasing the effects of the latter: all the draughts, with one exception, were vomited instantly. We, therefore, think it proved that the medicine exhibited did not exercise an injurious action on the unfortunate patient. At the same time, sympathizing deeply with the sufferings undergone by Dr. Gurney—who is, we understand, a talented physician, and a graduate of the University of Pisa—we cannot but regret that the body was opened at so early a period after death, and that a chemical examination of the contents of the stomach was not entered into. The calumnies which this unfortunate event has given rise to having found their way into the public press, we have considered the publication of the entire transaction, and the refutation of these calumnies, as a duty we owe to the readers of the *Medical Times*, to the profession generally, and to Dr. Gurney himself, with whom we are totally unacquainted, but whom we should wish to screen from further annoyance.

D. McCARTRY, D.M.P.

Scrofulous Ophthalmia.—Dr. Morand, of Tours, views this disease as coincident with inflammation of the pituitary membrane. He has always found the interior of the nasal fossæ red and swollen, sometimes even to the upper part of the lip. The mode of treatment consisted in applying caustic to the interior of the nostril on the side corresponding to the affected eye, for the first week, twice a day—after this, once a day, and then every second or third day. The nitrate of silver can be used, either in the solid form, in solution, or as an ointment. He says that when the swelling of the upper lip assumes an eczematous character, the nitrate of silver cures when all other means have failed.

Lithotomy Superseded.—A surgeon, named Cerveiller, is said to have succeeded in dissolving calculi in the bladder by the use of electricity.

The Use of Digitalis.—The heart and kidneys are the two organs which this drug principally affects. Dr. Munk states, that the tincture affects the heart—the infusion, the kidneys. The tincture must be given alone, to lower the action of the heart—in combination with antispasmodics, to relieve palpitations and dyspœia. As a diuretic, the infusion should be given in doses from half an ounce to an ounce every six or eight

hours, with moderate exercise and warm bathing to the loins, avoiding diaphoresis.

Burns treated with Ammonia.—Mr. Giffard recommends a concentrated solution of caustic ammonia to be applied to the injured part by a compress wetted with it. The application speedily relieves pain, and must be continued for half an hour. After this, no other dressing is required.

Hæmorrhage from Leech Bites.—In order to arrest this, an ointment composed of six parts olive oil and two or three parts of yellow wax has been used, spread thinly on linen and applied to the orifices.

Sheep's Brains a powerful Styptic.—M. Dupuy has found that the cerebral matter of the sheep possesses in a high degree the property of coagulating blood, and of immediately arresting hæmorrhæge. He states further, that the brain of the sheep kills animals more rapidly than corrosive sublimate.

Diaphtheritis.—Dr. Morand recommends a lotion composed of one part of nitrate of silver and three parts water, to be applied three times a day to the seat of the disease, and thinks, if this should fail, there is no resource left but the operation of tracheotomy.

The Reduction of a Dislocated Shoulder facilitated by the Employment of Ether.—At the Hôpital d'Aix a stout muscular man was admitted with a dislocated shoulder, whose reduction had been attempted the day before without success. In the hospital the house-surgeon was unable by the ordinary methods to reduce the dislocation. M. Bourquet administered the vapour of ether, and at the moment when intoxication manifested itself, began extension and counter-extension, when the head of the humerus immediately slipped into its place without any sudden jerk, and without the knowledge of the patient.

Injection of Ether into Arteries.—Baron Flourens, having made some experiments on the injection of ether into arteries, has discovered that the motor power disappears before the sensitive, while in inhalation the order is reversed.

REVIEWS.

Curabilité de la Phthisie et des Scrofules, appuyée sur des Preuves Authentiques. Par A. M. BUREAU D'ROFARY, Docteur en Médecine de la Faculté de Paris. Paris: Germer Baillière. London, Baillière. 8vo., pp. 216. 1847.

The question as to the curability or incurability of phthisis is one in which the profession has long been at issue with itself. By some practitioners, who would grumble mightily were their pathology doubted, any tubercular degeneration of the lungs is considered as fatal as hydrophobia; by others, on the contrary, also tenacious of their pathology, consumption in any of its states is a comparative trifle, and they advertise, and testify to, its curability with as much confidence as a man will speak of the quality of a hat, and the probable wear of it. We are very much inclined to the opinion that, of the vast numbers of men who profess to be adepts at detecting phthisical lesion, not a few are really novices at the task; and of those who may be thus far competent, how many are there who know what phthisis actually is, in the cases that variously betray its evidence? Every man must use a stethoscope—in how many hands is it better than a penny trumpet? Every man can talk of tubercles—how many are there who know the pathological meaning of the word? It is the absence of definite information, diagnostic and pathological, concerning phthisis, that constitutes the utter worthlessness of the majority of writings upon the subject. The late researches of morbid anatomy, microscopic and chemical, have constituted an era in the science of medicine, and in no department of it more so than in that which relates to the prevention and cure of phthisis. That the phthisical lesion can be prevented developing itself, even amongst those who have a constitutional predisposition to it;

and that, after having commenced, its ravages can be retarded for a time, or for ever, are facts well-known in the experience of the enlightened members of our profession. But these good results are obtained by no single set of means—by wearing iron collars; by flaying the skin from off the chest; by breathing medicated vapours; by blowing wind instruments; by swallowing homoeopathic doses of physis; by drenching with cold water; nor of feeding upon Morrison's pills. Yet there are certain hygienic rules, and certain processes of treatment, local and general, which exert a marked influence upon the physical tendency and taint. Many of these are excellently set forth in the volume before us; they are very lucidly and scientifically given; and clearly indicate that their author is no stranger to the difficult subject he has chosen for his reflections. The work bounds with valuable practical comments, and is, moreover, enriched with a great number of cases that have a very orthodox bearing about them. Our author inclines, as do we, to the belief that tuberclescence of the lungs, commencing or commenced, is not necessarily the fatal affair many practitioners would make it; and he gives many valuable examples, from various sources, in proof. At the same time, he has no specific for consumption—his treatment is ancillary to that of nature. So much do we like the work, that it is not improbable its translation, wholly or in part, with annotations, may hereafter have a place in the columns of the *Medical Times*.

An Essay on the Tongue in Functional Derangement of the Stomach and Bowels, and on the Appropriate Treatment. By EDWARD WILLIAMS, M.D., Senior Physician to the Essex and Colchester Hospital. 2nd edition. 8vo. London: 1846. Simpkin and Marshall. Pp. 236.

In the preface to this work, in other respects well written, Dr. Williams has fallen into the strange blunder, we fear catching, of speaking of himself in the first person plural. This freak of literary absurdity seems to be having a run, as newspapers say of popular exhibitions, for Dr. Williams is not singular in it. We are, however, not inclined to let him pass unreprimated, seeing that, in the generality of his volume, he has given plenty of scholastic proof of being superior to the weakness we speak of. According to the title-page, this work was written by Dr. Williams, singly. We believe it. In the preface, therefore, as no other name is mentioned, we conclude the same single authorship is at work—that is, that Dr. Williams, *per se*, has written the preface. Then why talk of *us* this, and *we* the other? The conventional advantage of speaking thus is accorded to editors and reviewers, who for the most part are nameless and unknown; but for a man to talk of himself as *we* is a sin against common sense and common truth which we cannot let pass without censure.

The work itself reflects great credit on the author's industry and ingenuity. He has evidently spared no pains to execute a task towards which he has long bent his inclinations. He is clearly an enthusiast on the subject of the pathological manifestations of the tongue, but still what he says is the result of a series of investigations which are placed before us with all the importance of numerical testimony. He furnishes a great number of tables, certifying to the morbid relations of the tongue to disease in general, and in particular, and from these deductions are drawn for the facilitating of diagnosis and treatment. That the state of the tongue is a most valuable guide in the detection of disease there can be no doubt. Generally speaking its importance is either underrated, or its indications are not understood. Still, all this granted, there can be no doubt that very different states of tongue are occasionally met with in the same disease, and the same state of tongue in different diseases. For this reason, as every experienced practitioner knows, it is not possible that the condition of this organ can be an unerring guide in diagnosis. Often enough the

tongue has been clean through the entire of the fatal course of scirrhus of the pylorus; and it is not uncommon to find a furred tongue amongst men who have never known stomach or intestinal ailment in their lives. We state these facts, not at all in opposition to the leading principles attempted to be established in the work of Dr. Williams, which in the main is excellent, but as showing the fallacy of trusting too utterly to certain indications, and believing their evidence constant.

We cannot conclude without saying that the volume before us does great credit to the ingenuity and industry of the author, and that we wish him a continuance of opportunity to further investigate his subject.

Seventh Annual Report of the Registrar-General of Births, Deaths, and Marriages in England. Abstracts of the Two Years 1843, 1844. 8vo., Lond., 1846.

Like its predecessors, a valuable mass of statistical evidence, both professional and general. We are happy to find from the present volume, that the object of the Registrar-General is being seconded, in the almost unanimous readiness of the profession to communicate whatever they know concerning the causes of death. This accumulated information cannot fail to be of great practical value, in determining the relative ratio of disease in this country at large, and in the chief districts of it. Not more than fifty of the profession have forgotten its proverbial liberality, in refusing to subscribe to the forms and ceremonies of registration. At the most the task is not a serious one for each individual, yet the evidence of the whole must prove of immense value. We trust that those who have hitherto objected to second the working of this excellent scheme will see the desirableness of giving it their co-operation ungrudgingly for the future.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct from the Office of the Medical Times to Annual Subscribers: sending by a Post-office order, directed James Angerstein Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

A HANDSOME PORTFOLIO for holding the "MEDICAL TIMES"—very desirable to those who would keep the numbers clean for binding, and easy of reference—may be had, by order of any Bookseller, or at the Office, price 5s. An allowance is made to the trade.

Juvenis.—1. There is no authorized formula in the London Pharmacopæia for solution of morphia. 2. Acidum hydrocyanicum dilutum P.L. contains 100 per cent. of anhydrous acid. 3. Dose at first should not exceed m. v. 4. The ear ought to be accustomed both to immediate and mediate auscultation.

A Subscriber.—Yes—when a poor person is known to be unable to pay.

X. Y. Z.—The General Medical Annuity Fund, Mr. Daniell, Secretary, Newport Pagnell.

Alpha, Pontefract.—We know of no act of Parliament on the matter. The judge will order a bill to be made of the medicines, &c., if an action should be instituted.

Mr. Henry Smith's paper on mercury last week contained an erratum: fifth line from the bottom, fourth column, for 3ij., read ʒij.

Dr. Hilbers, Norwich, says, in a note to us—“My eye has just alighted on an inquiry, in one of the back numbers of the Medical Times, from a correspondent, and repeated by yourself, wishing to be informed of the source from whence I derived my information that the African fever had been successfully treated by the homoeopathic medicines? You shall receive, in a few days, all particulars.”

Mr. Wm. Brown, Ion-square, Hackney.—We cannot give the address.

Alpha.—Not that we know of. Dr. Wright's lecture may be obtained of any bookseller if properly described.

Fusbos.—There are many good points in the letter, but without a little alteration it would hardly suit our pages.

A Surgeon.—The pupil cannot be forced to serve the remainder of his apprenticeship after the age of twenty-one.

First-Session Man.—Apply to the Secretary of the Society of Apothecaries.

Mr. J. F. P'Anson.—Attention will be paid to the letter.

Boothia Felix.—Vessels engaged in the Greenland whale fishery invariably take a medical officer. London or St. Katharine's Docks, places of departure. Appointments in the hands of agents or brokers.

A Physician.—It would be premature, with only the outline of the bill before us, to state exactly the nature of the appointments.

We have received communications and letters from Mr. Wm. Edward Coyte Bishop; Mr. Wm. Smith, Delper; Mr. Hugh Fraser Haake, Mornington-house, Chiswick; Mr. Thomas Hunt, St. Day, Cornwall; Mr. Edwards, Sidney-place, Brompton; Mr. Smith, Burnar, Wisbeach; Mr. R. Poulter, Cambridge; A Constant Reader; Mr. H. Hurdwicke, Henyhall, Norfolk; A Dispensing Chemist, in the neighbourhood of the West-end; A Friend.

THE MEDICAL TIMES.

SATURDAY, MAY 1, 1847.

THE MEDICAL PROFESSION AND THE WITNESS-BOX.

It was the complaint of Pliny to Trajan, that whereas crimes were wont to be the burden of the age, now laws were so; and that he feared the commonwealth established by laws would in turn be subverted by them. Doubtless, good enactments are necessary to the diminution of crime, consequently to the security of the subject. In civilized society, natural liberty is resigned, in order that nothing may be done inconsistently with the interests of the community to which we belong. We give up our liberty that other men's may not be unduly curtailed, and that the whole body politic may enjoy such a freedom as is consistent with the safety and happiness of each. Laws enacted with any other object in view than these cannot be called good, but must be oppressive to true liberty, and dangerous to the stability of a government.

Equally necessary is it to the prosperity of a people that the laws be not only good, but that the manner in which they are administered be in accordance with the dictates of humanity and justice. The mere punishment of an offender because he is such is not what is required—this would be vindictiveness; but it is to apply the law with such an even hand as shall, so far as it is possible, prevent the repetition of that which renders a man obnoxious to punishment.

There are very few who break the laws of their country but do so with the hope of avoiding detection, or, if caught, with the hope of escaping retribution. Certain justice is what is desirable, because it would do more for the suppression of crime than punishment carried even to the destruction of life. A prisoner knows there are contingencies in his case. The law has its meshes, and the ingenuity of counsel is oftentimes sufficiently great to open them wide enough for an assassin to get through. Trial by jury has most important advantages, but, like all human institutions, it is not without defects. It is a popular

assembly, and a man, when he enters the box, cannot entirely divest himself of those passions and prejudices which he has acquired in his daily engagements in the world. The gentlemen of the bar know this, and act upon it in their examination of witnesses, and in their addresses to the jury. According to a common maxim the prisoner must always have the benefit of a doubt, and there are some men put into the jury-box who, by the exercise of forensic eloquence, may be made to doubt almost everything—even their own existence.

This seems to be especially the case when a prisoner is arraigned on the charge of murder. If found guilty he must die. And what so sacred as human life? Nothing short of the clearest evidence can warrant a jury to utter the solemn word guilty, or the judge to put on the black cap indicative of the prisoner's fate. And every kind of stratagem is employed by his counsel to avert the terrible catastrophe. Facts are dissected so finely that they appear to lose the very semblance of truth. Witnesses are handled so severely in order that their testimony may be considered as scarcely worth a straw; and proof the most palpable must be rejected from the uncertainty of all human things, and lest the mark of innocent blood should be enstamped upon the mind with a stain so indelible that nothing can ever efface.

We have made these remarks in consequence of what has recently taken place in trials of individuals charged with the crime of murder. With any other evidence than the medical, which of course includes the chemical, we have not now to do. There are very few instances of violence to the person, whether it result in death or not, that a surgeon is not summoned to attend; and, if the matter be brought before a judicial tribunal, then upon the evidence which he gives does the fate of the prisoner greatly depend. In the witness-box the medical practitioner has to support the dignity of his character, as well as to promote the ends of justice; to appear, in the view of the public as well as in the chambers of the sick, a man of science and experience. He has oftentimes to state facts which could only be elicited by sound professional knowledge; and, having announced them, to be well prepared for their defence. It should never be forgotten that medical evidence is exposed to numerous and, apparently, weighty objections; that those skilled in forensic warfare are so keen-sighted as quickly to discover any weak point, and so resolute as to leave no effort untried to carry it, that from this vantage-ground the entire testimony may be ruined. The surgeon may be a good practitioner; but, to come out unscathed from the witness-box, he must be a respectable medical jurist. It is from deficiency in this particular department of education that the members of our profession now and then cut such a sorry figure before judge and jury, and that gentlemen of the bar receive with so much suspicion the truths which are deduced from scientific investigation. True it is, as Mr. Justice Maule observed, in the Pontypool poisoning case, "that the evidence of medical witnesses is not like the statement of an eyewitness, who might, for instance, see another person on a road;" but is what his lordship subsequently stated true, that "their evidence was generally a matter of conjecture, of guess, which their scientific knowledge enabled them to make." Real science has little to do with guessing—as little as "inflammation of a few hours' duration in producing scorching or burns

of the lip, and corrosions of the mucous membrane of the throat down to the stomach, so that it could be easily removed by being scraped with the nail." Of a truth it is no very pleasant thing to be rebuked by a judge, and browbeaten by counsel, when we stand up to state "the truth, the whole truth, and nothing but the truth."

The opinion which gentlemen of the bar seem to entertain of the progress of medicine and its collateral sciences is one which reflects no credit upon them as individuals of exalted minds and liberal education. Surely they have not closed their eyes against the admission of that light which has dawned upon us, and which is steadily advancing to the brilliance of meridian splendour? We can make some allowance for counsel, in the exercise of their vocation, who make efforts, even at the expense of science, to free their clients from the stern inflictions of justice; but we are struck with amazement when we hear a judge say, in reference to scientific truth, "that it is a matter of opinion, and not a matter of fact"; and still further lessening its importance (though it might have been unintentional) by adding, "that he had heard that medical science had made rapid and wonderful advances during the last twenty years. So, he dare say, it was said twenty years ago, and so it would undoubtedly be said twenty years hence; and probably the science would never arrive at perfection." Very likely; but then it does not follow that it is all uncertainty now, and that the evidence it offers must be received with suspicion. Mr. Cooke thanked goodness he was not brought up to the profession of a country surgeon; and well he might, if he were to be frequently put into the witness-box to be examined by such a scientific gentleman as himself. With such a degree of medical and chemical knowledge which the members of the bar appear to possess, it is no marvel if they imagine wet graves to abound with arsenic, and illegitimate children to be especially subject to fits.

The witness-box should ever be kept in view by the members of our profession; and the transactions which have taken place there should be carefully engraved on the tablet of the memory. Medical jurisprudence is not simply an ornament to professional education, but a something which may prove of sterling benefit in the active engagements of life: it prepares us not only to give our evidence before a legal tribunal in the best manner, but enables us to repel, as we ought, those attacks upon science which are occasionally made to accomplish some particular object.

Many of the scenes which have been exhibited in the trial of individuals charged with capital offences have had their origin in a reluctance to take away life. Public opinion is not without its influence upon the members of the bar; and juries are ready to seize the most trivial circumstance to free their hands from the stain of blood. If the law is at fault, it is the duty of the Legislature to engage in its correction. With the question we have nothing to do; but we must protest against medical men being made scapegoats for culprits, or that science, because it has not yet arrived at perfection, should be treated as a thing of little value.

MEDICAL SERVICE IN THE ARMY AND NAVY.

A few days ago General Sir Howard Douglas, in the House of Commons, called attention to the cases of the medical officers who have not

been included in the warrant issued in July, 1846. Officers of a certain standing in the service had conferred upon them, by the warrant of 1840, important advantages—that of full pay on their retirement. The warrant of 1846 increased the retiring allowance to quartermasters and veterinary surgeons, but paymasters and medical officers were still forgotten. Sir Howard very properly urged their claims, upon the principles of justice, and he showed that, from want of proper retiring allowance, medical officers and others were compelled to cling to the service when their physical and mental powers were weakened, and, consequently, when it was injurious to the service not less than to their own comfort to remain. The medical officers, as was stated, differed materially from the others. True, the former do not purchase their commissions, but large sums are expended in their education, and the arduous duties of thirty years cannot be efficiently discharged without subsequent suffering. At the age of twenty-four a surgeon enters the service, and at fifty-four he is certainly entitled to such an allowance as will administer to his ease and enjoyment in the few remaining years of his life. Colonel Lindsay contrasted the situation of surgeons with that of other officers. The latter may receive commissions when only sixteen or eighteen; the former cannot enter upon their duties till twenty-three or twenty-four; making a difference of five or seven years, when they become entitled to their respective pensions. The one, when engaged in foreign service, might return home; the other could not, but must be found constantly at his post. Nor can it be said that the profession of the military surgeon exempts him in the least from the fatigues and dangers of war. His office is no sinecure, but one where (compared with others) he gets few rewards with abundant labour. Mr. F. Maule, or any other Secretary-at-War, may feel it a very unpleasant thing to discuss matters of this description, yet it is but fair that there should be a proper amount of regard paid by the Government to every deserving servant. We admit that the labours of the surgeon are less ostentatious than those of other military officers. He takes the charge of the field after hostile squadrons have measured their strength, and is there installed generalissimo of the whole army of maimed and wounded, and commander-in-chief of tourniquets, bandages, and knives. The note which summons him to duty is the wail of human suffering; and the music which accompanies him in his progress is the sighs and groans of those who are ready to perish. And yet there are no gaudy ruses, so pleasing to flesh and blood, in reserve for him—no high-sounding titles to inspire the multitude with awe, or brilliant stars to excite their admiration; nor are we aware that, as yet, the Government has been able to spare even a small piece of ribbon to adorn the button-hole. In France they have set us a good example, for there honours and titles and substantial rewards are sometimes bestowed upon eminent medical men; while here, the highest honour to which they can aspire is the title of *equus auratus*, and the greatest reward a pension to the amount of about 15s. a day. Our brethren in the army and navy are surely entitled to a little more; and we should rejoice to see the heads of the two departments using their powerful influence to remove many of the evils of which there is just reason to complain, and to procure a further recognition from the Government of the claims which honourable and lengthened services have upon its liberality.

Sir Howard Douglas and Colonel Lindsay have done good in drawing the attention of Parliament to the niggardly rewards which medical men receive when retiring from active duties in the army and navy; and we hope, ere long, to see that their effort has not been lost upon those who are able to lend a helping hand.

MISCELLANEOUS CORRESPONDENCE.

CHEMISTRY AND MEDICINE.

[To the Editor of the Medical Times.]

SIR,—We cannot have a more lamentable proof of the present distracted state of the medical profession, speaking politically, than the fact that a considerable portion of the valuable space of the weekly periodicals is invariably filled with all sorts of intolerance and abuse on the part of some one section of that profession against some other. Your paper of last Saturday contains two letters which are striking examples in point. Allow me a few observations on the subjects which so sorely disturb the peace of mind of your two correspondents.

The existing state of matters among us may be illustrated as follows:—

Jenkins, Tomkins, and Popkins are fellow-students. They have all served precisely the same kind of apprenticeship, they lodge in the same house in town, they go arm in arm together to the same lectures and hospital practice, they assist one another in their studies, they read the same books, &c. &c. After two or three winter seasons thus spent together, Jenkins having more brains than money, and knowing the law, goes up to the Hall, passes an examination in anatomy, practice of medicine, midwifery, medical jurisprudence, chemistry, materia medica, pharmacy, botany, &c., and is duly licensed to practise. Tomkins having more money than brains, and either disregarding the law or thinking it a "more gentlemanly affair than the jalap-and-rhubarb botheration at the Hall" (that botheration being of some little consequence, by-the-by), goes up to the College, is asked a few questions in anatomy and surgery only, and receives what Mr. Lawrence says is merely a testimonial signed by some hospital surgeons conferring no privileges whatever. Popkins, having brains and money both, passes both institutions. Our three friends now commence practice as general practitioners, and then begins the row. While Tomkins is busy making up pills and corking bottles, he takes occasion to tell his gaping patients that Jenkins does wrong in styling himself "surgeon"—that he is only an *apothecary*, a thing very little better than a grocer, and not gentlemanly at all; and he writes to the journals raking up old-world ditties about 'pothe-car-ies, complaining at the same time that the law does not sanction his practising as the very functionary whom he thus affects to despise. Jenkins is naturally indignant at his old friend who thus shows his ingratitude for the grinding he had often bestowed upon him, and says that Tomkins has no right to practise at all. While Popkins turns up his nose at both the other two, and, forgetting that he is throwing dirt at his own qualifications, asserts that they are neither of them qualified to practise, and loudly proclaims his own exclusive right to be looked upon as the genuine Stilton. Surely two quacks do not make one doctor, any more than two asses make one lion; but perhaps Popkins, mindful for once of Lindley Murray, would maintain that two negatives make an affirmative. Thus, at New York, it is no unusual thing to hear two negroes abuse each other nearly in the following language:—"You dam black nigger you!" For Heaven's sake let us not laugh at Sambo any more.

To your correspondent "Chirurgus" I would venture to observe that he clearly misunderstands the matter. The Apothecaries' certificate is un-

questionably the *only legal* qualification in England—meaning by the term "legal" a qualification protected by an act of Parliament. The Council of the National Institute think, with "Chirurgus," that this is not fair to the members of the College, and wish, equally with him, to place them on the same footing in the eye of the law as the licentiates of the Hall; sympathizing with him in his desire to be allowed to practise as that unclean thing, the "potheary," and being willing, equally with him, to take the curriculum of the College, and not the examination, as a test of sufficient acquirements. I would also observe to "Chirurgus," that the less said the better about this same curriculum, unless he address his remarks to the *marines*. I know a young *druggist* who passed the College last year after only one year and three weeks' attendance on lectures and hospital practice. It is well known that since 1843 the whole affair, as far as the membership is concerned, is neither more nor less than a *little-go*.

Your anonymous correspondent, at page 164, is such a very slashing reformer that I hardly dare encounter him. Like Popkins, he won't hear of anything less than what is absurdly called the *double* qualification; and he gravely proposes in one breath to prohibit Sir Benjamin Brodie from practising, and to annihilate the continental universities; though he does not hint at the kind of authority he would make use of to effect the latter object.

Surely, Mr. Editor, these unhappy divisions will soon cease from among us. Let the M.R.C.S. consider that the ancient connection between the grocers and the apothecaries has as little to do with the present state of things as the better-remembered alliance between the barbers and the surgeons; and that, if he furnishes medicines to his patients in medical cases, he is himself quite as much a 'potheary as any one can be now-a-days; he ought to remember, too, that if he denies to the L.S.A. the right to style himself "surgeon," he may himself be asked by what right he styles himself a *medical* man. I would also beg the practitioner who rejoices in the possession of two diplomas to reflect that the same studies and the same certificates, with very trifling exceptions, having enabled him to present himself for examination at both College and Hall, he cannot, without depreciating the value of his own acquirements and qualifications, maintain that his fellow-student who possesses *either* diploma is unfit to practise.

I am, Sir, your obedient servant,
April 15.

USE OF ETHER.—MRS. PARKINSONS CASE.

We have received a communication, with a copy of the *Hampshire Independent* containing a letter from Edwin Hearn, Esq., M.B., formerly house-surgeon to University College Hospital, in reference to the influence of the vapour of ether in producing the death of the unfortunate Mrs. Parkinson. After mentioning the constitution of the patient, the malady under which she laboured, the trials of the ether previous to the operation, and then the tedious operation itself while the patient was but partially under the influence of the vapour, he goes on to say:—

"The account of the *post-mortem* examination is very unsatisfactory, since we find that those important secretments, the kidneys, were not even examined. I believe that I am borne out by high authorities in stating that many of those patients who sink rapidly after severe operations do so in consequence of the renal secretions being carried on imperfectly. The only abnormal condition noticed was congestion of the membranes of the upper part of the anterior lobes of the brain, with the exception of the blood being in a fluid state throughout the body. From the report there were no symptoms specially referable to the membranes covering the anterior portion of the upper part of the brain during life. With regard to the fluid state of

the blood, I should account for it in the following manner:—A given quantity of blood being lost during the operation, it would have the effect of partially emptying the vessels, to obviate which the absorbents quickly replenish the vessels with a fluid of a diminished consistence; and patients after operations not being able to take any food but thin fluids, this condition would necessarily be kept up for a time, and restored to its natural state in proportion to the rapidity of the patient's recovery. In the case in question, from the description given, the blood would have been naturally poor and thin, and in the disease under which the poor patient laboured, if I remember aright, defective in red particles, according to the analyses of Andral and Gavarret.

I myself remember a case very similar in many respects to that under consideration, although in this instance, I believe, life was happily preserved. The patient, a strong middle-aged countryman, apparently in excellent health, applied to the Taunton Hospital, to have a tumour weighing about one pound removed from the back part of his thigh. The operation was performed without much loss of blood, but it occupied the greater part of an hour in performing. He was so depressed by the shock, &c., that for many days his life was despaired of, brandy, ammonia, &c., being required to sustain him. I left the neighbourhood whilst he was under treatment. This patient had not the disadvantage of contending with a malignant tumour, and the state of health consequent thereon; his was of the simplest kind, yet he nearly lost his life in consequence of the operation, notwithstanding no other had been administered.

"Southampton, April 8."

[To the Editor of the Medical Times.]

SIR,—Your correspondent "Chirurgus" informs your readers that the "apothecaries," in the reign of James the First, were associated with the "grocers"; but shortly afterwards the "apothecaries" obtained a charter for themselves, and by degrees got into the habit of prescribing medicines without having recourse to the physicians.

No doubt, Sir, these "apothecaries" not only prescribed medicines, but acted in the capacity of the "general practitioner" of the present day; and, this arrangement being found to suit the convenience of the public, the act of 1815 was passed; and no doubt the gentlemen then in practice were placed on a sound footing as "medical" men, or "apothecaries."

This act of 1815 committed no retrospective injustice—it legalized all then in practice; it made them legal "medical" practitioners, simply because they had committed no breach of the law hitherto: this act being the first step in legislation for "medical" practitioners.

It results from the act of 1815 that all who have commenced "medical" practice since that date, without obtaining the necessary certificate, are illegal "medical" practitioners, as stated by the deputation to Sir George Grey; and they have no right to complain of this fact, for they have placed themselves in this position with their eyes open, and in defiance of an act of Parliament only thirty-two years old.

It is quite true, as stated by your correspondent, that many gentlemen pass the Hall and commence practice as "general practitioners" under the title of "surgeon"; and no doubt, Sir, their reason for doing so is simply because it is not illegal; there is no act of Parliament to prevent it; and they trust that, when the representatives of the nation legislate for "surgical" practitioners, the same course will be pursued as in 1815 with the "medical" practitioners, and no retrospective injustice be committed.

As your correspondent tells us the "apothecaries" were once associated with the "grocers," he might also have added, that the "surgeons" were once in league with the "barbers," and that they (the surgeons) afterwards obtained a charter for themselves, in the same manner as the "apothecaries," or "medical" practitioners did. The "surgical" practitioners have not yet

completed a parallel case with the "medical" practitioners, by obtaining an act of Parliament relating to "surgical" matters equivalent to the act of 1815, which regulated "medical" practice only. It is plain, then, that "Chirurgus" is liable to an indictment for a misdemeanour for illegal "medical" practice, equally as well as Ellis Flitcroft, who was convicted of a similar offence, at Bolton sessions, on the 3rd instant; but it is equally plain that the licentiate of the Hall commits no offence against the laws by engaging in "surgical" practice. Now, Sir, I think the proposition of the "National Institute," for the incorporation of the general practitioners (who possess any British diploma) in a new institution, as the fairest mode of reconciling the various interests in the profession; it will make "Chirurgus," and all the parties mentioned by the deputation to Sir George Grey, legal and honest individuals, no longer liable to be indicted as criminals; and in return for this boon, and the legal competition of a numerous class of well-educated men, the Apothecaries' Company naturally and fairly ask that their licentiates be confirmed in privileges which they at present exercise, without breaking the laws of their country.

Your well-known impartiality induces me, as it did "Chirurgus," to expect your insertion of my remarks.

I remain, Sir, your obedient servant,

L. A. H. (1839),

And Member of the National Institute of Medicine, Surgery, &c.
Durham, April 19.

HOSPITAL NEPOTISM.

[To the Editor of the Medical Times.]

DEAR SIR,—The remarks in one of your leading articles in this day's *Medical Times*, directed against the system of nepotism, are worthy of notice, and undoubtedly correct in the main; but they are certainly calculated to give a false impression as to the relative merits of, and the nature of the influence used for, the respective candidates. Whilst one would be greatly assisted by the patronage and support his uncle could command, the other owes his election to a family contingency, he having married a relative of Loyd, of the firm of Jones Loyd and Co., the very influential bankers of this town. The kind of influence likely to be brought to bear upon the merchants of this town may be easily surmised; and that it was to its utmost extent exerted I know.

Though Mr. Smith would have been elected by the prevalence of a system which has often been employed to a baneful result in other places,—a system the sooner exterminated the better; soon may the day arrive when a purer and a better shall prevail,—yet the profession here, I believe, would be nearly unanimous in the opinion that he would not be unworthy of the office. At the Medical School of this town he distinguished himself. Afterwards he held the office of house-surgeon to the Infirmary, and creditably performed its duties. As a demonstrator at the Medical School he performs his part in a manner highly to be commended, so much so as to have secured a tangible testimonial of respect from the pupils in the form of a purse of gold. With the candidates personally I am alike unacquainted, and thus much I have said to put the matter in its true position, being persuaded that your strictly just, gentlemanly, and honourable, but always disinterested and independent, and, when needs be, unflinching, predilections will appreciate the information.

I am, yours truly,

A. W. C.

Grosvenor-street, Manchester, April 17.

P.S.—I was myself requested to become a candidate, and might have come to the goal the third, fourth, or fifth; but not liking the hubbub and bustle, and not thinking the object worth the outlay, and, above all, hating the means obliged to be resorted to, I declined; and, under the im-

pulse of the moment, drew out the following address, which I did not, however, publish, as I remembered the fable of "The Fox and the Grapes," to the application of which I might have been exposed:—

"To the Trustees of the Manchester Royal Infirmary.

"My Lords, Ladies, and Gentlemen,

"Patronage in the form of family influence, or the private friendship of persons of influence, or partisanship, has ever exerted an unfair and sometimes a baneful bias in the appointment of medical officers to the charitable institutions of this country. In illustration of this remark, fix your attention upon the progress and result of the present contest for the vacant surgeons'hip to your Infirmary.

"A better state of matters (the *concours*) prevails on the Continent.

"Recommendatory certificates, particularly of metropolitan surgeons, are too frequently given without proper consideration—so often indeed as to make it a rule rather than an exception.

"From the rapidly advancing improvement now going on in the development of the public mind, we may hope that the time is near when such influences will be in abeyance. When that period or its dawn arrives, as a candidate for your suffrages, and with the prospect of success, I shall present to you those proofs of industry and eminency in my profession which it is my happiness to possess."

"I am, &c. &c."

GROVE-HALL ASYLUM.

[To the Editor of the Medical Times.]

SIR,—Observing in the *Medical Times* of the 21st inst. a full report of the proceedings at the Thames police court, and some editorial remarks, respecting the death of a pauper patient in this asylum from ill treatment by the attendants, I beg to send you the following copy of a letter on the subject from the Commissioners in Lunacy, which I trust you will do me the favour to insert in your next number, as showing the part taken in the investigation by the proprietor and myself.

I am, Sir, your most obedient servant,

EDWARD PALMER, M.D.,

Bow, April 28.

Medical Superintendent.

"Office of Commissioners in Lunacy,
19, New-street, Spring-gardens,
April 22, 1847.

"SIR,—The Commissioners in Lunacy considering the publicity that has been given to the circumstances attending the death of William Rank, a pauper patient in your asylum, and the committal of two of your attendants for manslaughter, direct me to express to you their satisfaction at the prompt way in which you, in the first instance, brought the subject under their notice, and also to the aid rendered by both Dr. Palmer and yourself throughout the inquiry.

"They direct me further to say, that the fact of both the inquest and the *post-mortem* examination having originated altogether with yourself and Dr. Palmer, is very creditable; and affords the best evidence of your desire to secure humane treatment to the patients in your establishment.

"I am, Sir, your obedient servant,

"R. W. S. LATWING, Secretary.

"To Mr. Edward Byas,
Grove-hall Asylum, Bow."

MIDDLESEX HOSPITAL.

The squabble at this institution still continues. On Wednesday there was an adjourned meeting of the court of governors, which lasted for five hours. Sir R. H. Inglis in the chair.

The first resolution was moved by the Hon. Captain Maude, and seconded by his Royal Highness the Duke of Cambridge; it was to the following effect:—"That the office of house-steward and secretary should be divided, the former person to reside in the house; the latter not."

The Duke of Cambridge in his speech observed:—"One great fault existed in the hospital which should be remedied. A committee should be appointed to see that the house-steward provided proper diet for the patients, and that the nurses were attentive. He complained of the inefficiency of the matron, the inferiority and even drunkenness of some of the nurses and the neglected state of the room for operations, which had not been properly heated for the last three years.

Mr. Fielder, in the midst of great confusion, endeavoured to set his Royal Highness right, and stated that it was only within the last year and a half that there had been mismanagement, and this was to be attributed to repeated quarrels among the medical officers.

Another resolution, proposed by the Hon. Captain Maude—to the effect that Mr. Tuson should resign his appointment as one of the surgeons—provoked a discussion which was protracted over several hours, and in which a great number of speakers took part.

Mr. W. Hawes, Mr. Labouchere, Dr. Hawkins, and Sir William Stirling, supported the motion; which was warmly opposed by Mr. Brewster, Mr. Bailey, and others. The resolution condemned Mr. Tuson in giving and antedating cards of admission to the lectures, but exonerated him from a corrupt or unworthy feeling. The resolution was carried by a majority of 51 to 33 votes.

WESTERN MEDICAL AND SURGICAL SOCIETY.

The first anniversary meeting of this society was held at their rooms in Sloane-street on Friday, the 9th instant.

The report of the council was read. It commences by congratulating the members on the success which has hitherto attended the progress of the society. There are upwards of sixty members; the library contains already more than 300 volumes; and the reading-room, which is open daily from ten in the morning till ten in the evening, has been regularly supplied with all the weekly and quarterly medical periodicals. The report proceeds to allude to the valuable communications which have been read at the monthly meetings during the past year, and the interesting discussions which have ensued, and dwells especially on the value of these meetings for promoting friendly feelings among the profession. It concludes with some suggestions, the result of a year's experience, for the future. The most important of these is, that the meetings should be held once a fortnight during the medical season, the monthly meetings being retained during the recess.

The report having been received and adopted, thanks were voted to the president and other officers for their valuable services during the past year, and the officers for the present year were elected.

Sir James Clark was re-elected president; Messrs. Dickenson and Lano, and Dr. Mansell, were re-elected vice-presidents, with Dr. Hardwick, of Kensington, in the room of Mr. Woolley—the laws of the society requiring that one of the vice-presidents should retire annually, and the lot having fallen on that gentleman. Mr. Woolley was elected a member of the council, with Messrs. Gaskell, Godrich, Keene, Mackintosh, Mould, Pettigrew, Pollard, Seaton, Synnot, Warder, and Wilson. Mr. Muller was re-elected treasurer, and Mr. Barnes, secretary.

A. B. BARNES, Hon. Secretary.

KING'S COLLEGE, LONDON.

The Annual General Court of this Institution was held, last week, in the hall of the building. The Bishop of Winchester presided.

The hospital, it was stated, had relieved in the past year 17,823 patients. A "Daniell" scholarship had been established for the encouragement of the science of chemistry.

The distribution of prizes and certificates of honor in the medical department took place on Saturday at three o'clock.

In the absence of his Grace the Archbishop of Canterbury, the chair was taken by the Bishop of London, who distributed rewards of secretarial industry to the following scholars and prize-men.

Senior Scholar.—Peter Eade	
Second year.—George Herbert Cusker	
Juniors.—Henry Hyde, John Wood, George A. Kinnear	
Anatomy	Prize—John Cox L. n. h. Certificate—Wm. Chas. Lake
Physiology	Prize—John Cox L. n. h. Certificate—2. Geo. A. Shupard
Chemistry	Prize—James Fox
Maternal Medicine	Certificate—John Cox L. n. h. Prize—Wm. Chas. Lake
Surgery	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Medicine	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Midwifery	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Botany	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Forensic Medicine	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Comparative Anatomy	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Medical Clinical	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Surgical Clinical	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Warwicks	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Leathes	Prize—Wm. Chas. Lake Certificate—1. Wm. Chas. Lake 2. John Cox L. n. h.
Associate.—John Thomas Ashford, Peter Eade, Walter Lott, Herbert Cusker	

To the above-named gentlemen the chairman addressed a few words of encouragement and compliment.

From the report read by the Dean of the Medical Department, the medical school of the college appears to be in a most efficient and satisfactory condition.

We understand that Sir Robert Peel has consented to take the chair on the ensuing anniversary dinner at King's College Hospital, which is to take place early in June.

JUDICIAL DIFFERENCES.

CORONER WAKLEY.
Coroner Wakley, in his summing up at the inquest on Miss Collier, said, that "He could attach no blame whatever to Mr. Corfield. He thought Mr. Corfield did, under the circumstances, what was perfectly right. He thought Mr. Corfield's conduct commended him from blame. . . He could not see that they (Messrs. Corfield and Bell) had done wrong."—*Pharmaceutical Times*, Feb. 27.

JUDGE COLERIDGE.
Judge Coleridge, at the trial of Dr. Cronin for the manslaughter of Miss Collier, said, "That, to say the least of it, the act of pretending to make up a prescription sent by a physician, without putting in all the ingredients mentioned in it, was most monstrous. Although not a fraud in the ordinary sense of the term, still it was one on the person for whom the medicine was intended. Such a proceeding was very dangerous in any case, and he was not prepared to say what the effect had been in the present instance. . . It appeared perfectly clear that a chemist, possessing the ordinary knowledge of his profession, must have known that a weak description of litter alone would be intended to be used for the prescription. Mr. Corfield did not appear to have known anything upon the subject, and he did

WAKLEY AGAINST THE MEDICAL TIMES.

COURT OF EXCHEQUER, Monday, April 26.
(Sittings in Banco.)

Mr Cockburn moved for a new trial in this case, which was tried before the Chief Baron at the sittings after the last term, when a verdict was passed for the plaintiff for £175, on the ground of misdirection.

This was an action of libel on the plaintiff, who is the member for Finsbury, and it appeared that this was a second action for the like cause between the same parties. On the first occasion the plaintiff obtained a verdict for £150, and the present action was founded on the publication, by the defendant, of the proceedings of that trial, and certain comments on the verdict, and its effect on the plaintiff's character. Among the passages complained of was one in which it was stated that "the plaintiff's character, under the skilful treatment of Mr. Denman, had had to struggle against the dire situation of the Hope Assurance-office." This paragraph, it was said, libel was not brought forward in the declaration either by precatory avowment or by innuendo, so that it was left to convey the construction and sense which the words might bear in their ordinary acceptation. Neither was it alluded to by the Attorney-General in his opening speech, or by him, Mr. Cockburn, in his address to the defendant, which proceeded on the principle of showing that the plaintiff had better have let the thing drop. The learned Chief Baron, however, it was now complained, had alluded to the paragraph in his summing up to the jury, observing that "though it had not been alluded to, he did not see any reason why he should be silent on the subject, and adding, that "though it might be difficult to deal with the allusion, yet in his opinion it was hardly decent for the defendant to allude directly after the trial to that which was a matter of history and all men might understand." This mode of pointing attention to that which the plaintiff had passed by in silence in his declaration, and in the speech of the counsel, was very likely to mislead the jury, and had a tendency to induce them to give more damages for that which formed no part of the plaintiff's complaint, for without any explanation or innuendo applicable to this paragraph it had no libellous meaning whatever. The effect of this might well be to work injustice, for if there had been any innuendo, the defendant might, perhaps, have been able to meet and justify the point so made.

The Lord Chief Baron. You may take your rule now. I have no recollection now of the manner in which I left the case to the jury, and should like, for my own information, to see the short and writer's note, if you have one, of my summing up; but I dare say you will find that the remarks complained of had reference to the argument founded on the alleged harmlessness of your client's remarks.

In the course of the learned gentleman's arguments, Mr. Baron Platt took occasion to remark, that, in his opinion, a libel meant a composition in which a man was illegally defamed, and that no man could say that he was illegally defamed by the fair and bona fide report of proceedings in a court of justice, which was open to all the world.

Mr. Baron Pake: Yes; a court is open, and it matters not how large it be made, or whether its proceedings are made public by publication to the world, if it be fairly done.

The Lord Chief Baron: I can very well conceive a case in which a fair report of a trial for libel might be made with the express object of republishing the former libel.

Mr. Cockburn. That, my lords, is a question which it does not interest me now to enter into. Rule nisi granted.

not give the prescription a fair chance."
Medical Times, April 10.

MEDICAL OBITUARY IN THE ARMY OF INDIA
REPORTED SINCE THE DEPARTURE OF THE MAIL OF MARCH 2.—HIS MAJESTY'S TROOP: Assistant-Surgeon W. Bowie, M.D., 78th Highlanders, at Belgaum, on the 14th of March.—MADRAS: Superintending-Surgeon C. Desormeaux, Hyderabad Subsidiary Force, at Secunderabad, on the 16th of February. Assistant-Surgeon A. J. Will, 31st Regiment, at Palnaticotta, on the 23rd of February.

OBITUARY.—On the 11th inst., at Worthing, G. P. Byass, Esq., surgeon.—On the 19th inst., at his residence, Finsbury circus, Thomas Bevan, M.D., in the 44th year of his age.—On the 19th inst., aged 28, Mr. John Ellison, surgeon, Great Homer-street, Liverpool.—Same day, aged 40, Mr. Richard Shorrocks, of Liverpool, surgeon.—On the 28th inst., Dr. Robert Masters Kerrison, at his residence, 35, Upper Brook-street.

ROYAL COLLEGE OF SURGEONS.—Gentlemen admitted members on Friday, April 23.—G. F. Jones, T. J. T. Williams, W. D. Eddowes, J. W. Hubbard, J. L. Weir, T. Armstrong, A. R. H. Padmore, A. S. Willocks, J. Ferguson, and W. H. Baylis.

CONSEQUENCES OF DEFECTIVE SURVEY.—Dr. J. Playfair states the loss from unnecessary death and sickness for England and Wales at £11,000,000, and the United Kingdom at £20,000,000. These are the items of expense which Dr. Playfair reckoned are incurred under the present system, or rather want of system—direct attendance on the sick, loss of what they would have earned, premature death of productive contributors to the national wealth, and expense of premature funerals. Dr. Playfair estimates the loss for Manchester at nearly £1,000,000, Mr. Hawesley calculates the loss for Nottingham at £300,000, Mr. Clay estimates the loss for Preston at £990,000, Mr. Coulthart takes the loss for Ashton-under-Lyne at £1,000,000, and Dr. Playfair considers the loss of this metropolis to be above £2,500,000, and estimates the total loss to England and Wales at little short of £11,000,000.

MORTALITY TABLE.

For the Week ending Saturday, April 21, 1847.

Causes of Death.	Total.	Average of 5 Winters.
ALL CAUSES.....	981	914
SPECIFIED CAUSES .	978	909

MORTALITY TABLE 226

COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the THEATRE OF QUEEN'S COLLEGE, Birmingham.

By SAMUEL WRIGHT, M.D.,

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Quakerian Natural History Societies of Edinburgh, &c.

Sequela of the influenza of last year; nervous debility; various pathological associations of it; treatment; value of change of air, or change of residence; phthisis after influenza; observations upon; bronchitis a sequela of influenza; case of, occurring in a subacute form in an old man; details; post-mortem appearances; comments upon it; nervous depression a prominent symptom in such cases; value of cautious treatment; character of the expectoration a guide; plugging of the bronchi by albuminous or mucous exudations; case of suffocation produced by a pellet of mucus; why asphyxia is more common in bronchitis than in pneumonia; case of acute bronchitis terminating by asphyxia; treatment best to be observed in such cases; value of copious expectoration; illustrative case.

GENTLEMEN.—Let me say a few words concerning the *sequela* of the influenza of 1846. In the majority of cases it passed off, aided by remedial means, and left no particular pathological state, or states, deserving of notice. Not unfrequently, however, continued debility was one of its consequences. This was chiefly seen in early adult life, and especially amongst females. Sometimes it was mere weakness, with nothing specially to mark it; again, it was associated with menorrhoea, with leucorrhoea, with menorrhagia, with loss of appetite, with profuse night sweats, or with troublesome cough. Most of these were difficult of management, but were best treated on a direct tonic and sustaining plan, with change of air, when this was obtainable. You will generally find that those of your patients who have suffered from epidemic disease, no matter what, will derive more benefit during their convalescence from judicious change of residence than from anything else. It is always desirable to remove them a convenient distance from the scene of their sickness; but when this is not practicable, a temporary sojourn, even in another part of the town, is not without its advantages. I have known a visitation to a neighbour's house do more good in a few days than all the tonic medicines that had been swallowed during as many previous weeks. In these cases, both moral and physical circumstances operate restoratively; and where the latter are not prominent, in reference to the advantages of good air and exercise, the other may in some measure suffice, by occupying the mind with entertaining and agreeable subjects.

When the cough was the offspring simply of debility, or rather of irritability arising out of this,

tincture of sesquichloride of iron, alone or with tincture of henbane, was of excellent service: to this was advantageously added counter-irritation of the chest, or sponging it twice a day with cold salt and water. In more than one case which I saw, phthisical signs and symptoms succeeded to influenza: whether the phthisis were a *sequela* proper, I am not able to say. I can easily understand that the nervous depression I have spoken of as a characteristic of the disease, and a consequence of it, might lead to tuberculous cachexia; and it is not improbable that in some cases this was the fact: in others, however, it might happen, and very likely, that the influenza did nothing more than furnish an opportunity for a latent disease to start into activity, or for a tendency thereto to acquire fresh means of development.

Of the several *sequela* of influenza, bronchitis was amongst the most common. Perhaps this may be regarded as one of the pathological features of that variety of the disease that is attended with cough. In general the pectoral symptoms of influenza rather correspond with irritation or inflammation of the bronchi than with any other form of local derangement. Should any other present itself, this is almost always secondary of the bronchial disorder.

The bronchitis, usually subacute, that remained after the disappearance of influenza, or occurred as a consequence of it, chiefly showed itself in old people. The case of Quiney will furnish you with a good example. He lay, you will remember, in the accident ward, where we were obliged to place him, because of the other wards being full. He was a singular old creature, this. He had numbered upwards of sixty-three years, of which six-and-thirty had been passed in the monotonous drudgery of stage-door-keeper to the theatre. For this lengthened period he had not only stood sentry regularly at the stage-door, but had as regularly slept in the theatre—going home only once a week, for the sake of changing his shirt, and perhaps giving himself what he would consider a washing. Yet, in all this lengthened intercourse with the theatre and its representatives, he never once saw a play: the history of his whole life did not chronicle one visit in front of the scenes—notwithstanding that he actually lived for thirty-six years behind them. I was first requested to visit the poor fellow at his own home, or rather at his wife's, on the 13th of February. I learned that he had suffered from influenza a

few weeks previously, and that it had left him with a troublesome cough. He was sitting propped up in an armchair, and was breathing with some difficulty. His surface was colder than natural, and slightly bedewed with perspiration; pulse 106, small and feeble; tongue furred, and brownish in the centre; no pain anywhere, except in the chest when he took a deep inspiration; cough very frequent, and attended with a difficult expectoration of diffuent mucous sputum, of variable colour—here white and opaque, there frothy, elsewhere yellow, and again greyish; but there was no albumen, and very few pus globules; the stroke sound of the chest was normal throughout, except inferiorly, where it was a little less resonant than natural; the respiratory sound was audible everywhere, but constantly marked by a whistling, sonorous, bubbling, or mucous rale, according to the situation in which the stethoscope was placed; he had been the subject of winter cough for years; bowels imperfectly open; renal secretion sufficiently copious and natural. He was ordered the following:—

R. Infusi calumbæ, ʒviijss.; sodæ bicarb., ʒj.; tinct. hyoscy., tinct. camph. comp., aa. ʒij.; M. ft. mist. cujus capiat coch. ampla duoter die.

R. Pil. coloc. c., extr. hyoscy., pulv. scillæ, aa. ʒj.; misce et divide in pil. xij. quarum capiat ij. omni nocte.

He was directed to put his feet into hot mustard and water, and go to bed early.

The next day he was very slightly better: his cough was not so frequent, and expectoration less difficult. His domestic accommodations, however, were so indifferent that I advised his removal to the hospital, and he became an in-patient on the 16th.

When we first saw him together, he was in much the same state as that I have described, except that he was weaker. You will remember, also, my mentioning that over one portion of the right lung, where the stroke sound was distinctly sonorous, there was a total absence of respiratory murmur. The fact was new to me in this case, and I told you that I thought the absence of the respiratory sound was due to a large bronchus, or a series of smaller ones, being plugged up with mucus, and thus preventing the transmission of air to the vesicular apparatus to which those channels led. The conjecture was probably right, for at our next examination the respiratory sound was perfectly distinct, where

the day previously it was quite inaudible. He was ordered the same pills as before, and the same mixture, except that, on account of his weakness, the mixture had the addition of three drachms of compound spirit of ammonia. The following further treatment was pursued:—

Adhr. emp. *Alytes sterno*. R. Syrup. papav. alb., syrup. *toluani*, tinct. *camph. comp.*, tinct. *scillæ*, aa. $\mathfrak{z}\mathfrak{ss}$.; *misc* fiat linctus, cuius cap. coch. unum parvum tusso argenteo.

On the following day he was no better: still weaker. The blister had not risen, and another was ordered to be applied immediately: hot water bottles to his feet. Had no sleep last night.

R. Liq. opii, sedat. m. $\mathfrak{x}\mathfrak{i}\mathfrak{j}$.; sp. *ammon. comp.*, sp. *eth. sulph.*, aa. $\mathfrak{z}\mathfrak{j}$.; *misc* *camph.*, $\mathfrak{z}\mathfrak{j}\mathfrak{ss}$. *haustus* cap. stat. contr. rem. ut antea.

The succeeding day he was in much the same state; he had slept, but was not refreshed in consequence, which was an ominous sign; the blister had not risen, and this was worse. It was clear we had very little vital power to deal with, and that the chances of salutary reaction were few. These were being lessened by an increased difficulty of breathing, diminution of respiratory sound, and dullness on percussion, over the lower part of each lung. The pulse was becoming more feeble, and expectoration more difficult; the surface was cold, and congestion was apparent in the fingers' ends, lips, &c. The ammonia was increased in his mixture; the strongest liquid ammonia was ordered to be applied to his chest (I personally superintended the application for two hours, without producing the least impression upon the skin); and wine was given at stated intervals; his bowels had not been moved during the day, and were tympanitic, so a turpentine enema was given. Nothing, however, roused the poor fellow, and he died on the 20th of February, seven days from the time of my first seeing him. In the *post-mortem* we discovered some old pleuritic adhesions at the superior portion of each lung; the left lung, inferiorly, was firmly adherent, by old bands, to the diaphragm. The lower half of the left lung was engorged with black blood, but it was not consolidated, and bloody spumosity escaped from it when incised: superiorly, it was less engorged, but excessively spumous when cut. The right lung was similarly, though less severely, affected. The bronchial membrane throughout was of a dusky red colour, and covered with a muco-purulent fluid, not adhesive, and in places completely filling the smaller bronchi. Not a trace of tubercle, or cavity, or consolidation, was found throughout the lungs. The heart was rather larger than natural, the left ventricle being somewhat hypertrophied, and its septum bulging into the cavity of the right. The latter was much thinner than usual, and its auricle was very thin and dilated. The right cavities of the heart were filled with a coagulum, firm, and the greater part of it deprived of colouring matter; the left ventricle was nearly full of black fluid blood. The brain was extensively congested superficially, and its membranes were slightly injected; at its base was a small quantity of fluid. The liver was mottled, but not uniformly. The spleen was the smallest I ever saw: it weighed only an ounce and three quarters. The other viscera were natural.

This case, throughout, presented a pathological feature common to the acute and sub-acute bronchitis of old people—viz., a tendency to depression. So striking was it in this instance that I did not even dare to venture upon blistering the chest until an increase of the ailment rendered such treatment imperative; so low, however, was the vital condition that the skin was quite unaffected by blisters, or the strongest liquid ammonia. His surface was cold when I first saw him, and it never once recovered a perceptible warmth. This symptom led me to think unfavourably of the case from the beginning; and, added to the weakness of the pulse, the expressed feelings of languor, and the age of the patient, rendered it necessary that remedial measures should be very cautiously pursued.

These are cases in which it is easily possible to do more harm than good. Active purging or bleeding (even local) would, probably, have killed him outright, or have considerably hastened his end. The objects to be obtained were to support the declining strength of the patient, to calm the cough and the irritation causing it, and to promote expectoration. These were attempted to be answered by the remedies prescribed, which were sufficiently active without being too much so; yet they failed to afford more than temporary relief, and the patient continued to sink. The condition of the pulmonary apparatus showed that the morbid action within it had not been very energetic. There was not the least trace of inflammation of the lungs, and even their engorgement was of recent occurrence, as shown by the signs afforded in auscultation and percussion, and by the fact that a slice of the lung rinsed in water quickly lost all its blood, and its texture remained in other respects healthy and entire. The engorgement of the lungs was clearly the stasis of deficient, not of increased, vascular action. The condition of the bronchial membrane itself proved that its inflammation had not been vigorous: there was no lymph effused, nothing but diffuent mucus, intermixed with pus. In active bronchitis, the mucous secretion is at first glairy like white of egg, and of excessive tenacity: as the disease advances, the sputa become more opaque, but retain their tenacity. This is one of the best diagnostic signs I know of for determining the intensity of bronchitis. So long as the matter of expectoration flows easily, you may be sure that the inflammatory action is not urgent: be mindful, under such circumstances, how you employ heroic remedies, and especially amongst old people. They soon sink under bleeding, under profuse purging, under mercury, digitalis, and debilitating expectorants.

The stasis of blood in the lungs, in this case, may in some measure have been facilitated by the condition of the right ventricle of the heart. From the thinness of its walls, its propulsive powers must have been very feeble; so that the least impediment to the flow of blood through the lungs, instead of being overcome by an increased action of the right ventricle, would make more and more difficult the expulsion of its contents, until at last their gradual accumulation would render the contraction of the organ impossible. It was just so in this case, as was proved by the fibrinous mass that filled the right auricle and ventricle. This had evidently collected slowly, and for some time prior to death, for nearly all its colouring matter had been absorbed: the removal of this is never a *post-mortem* process. The patient, however, did not die of asphyxia, for there were no signs of this during life, and the superior portion of each lung was sufficiently permeable both for respiration and circulation. Had the right side of the heart been of natural substance and strength, it is not improbable that the disease might have had a favourable termination.

The size of the spleen was quite a singularity nor have I any opinion to offer upon it.

The plugging up of a large bronchus by a mass of lymph or thickened mucus, as happened once in this case, is not uncommon in bronchitis. But it is chiefly seen in the acute bronchitis of adults, when the secretion or exudation is thicker than in old people. It interrupts the passage of air to a particular portion of the lung, over which, in consequence, there is a natural stroke sound, but a total absence of respiratory murmur. Sometimes, before you leave the patient, a fit of coughing will remove the obstruction and tell you what it was. When the substance is of considerable size and firmness, it is often expectorated with much difficulty; and cases have happened in which the patient has been suffocated by the impaction of the foreign body in the trachea or some contiguous part. The pellet of mucus contained in the bottle I show you was taken from the body of an old woman, in whose *rima glottidis* it was firmly fixed. The case was one of chronic bronchitis

that presented only the ordinary features: one day, in a violent fit of coughing, she suddenly threw back her head, clenched her hands, struggled violently, and in a few seconds was dead. She was suffocated by the impaction of this foreign body in the little aperture I have mentioned.

The case of Quiney is a pretty fair type of subacute bronchitis, in the generality of its prevalence amongst old people. When subjects in advanced life suffer fatally from this ailment, they generally sink from the depressing effects of it, without any pathological condition having occurred sufficiently to account for death. In younger people, however, it often happens that, during an attack of bronchitis, death results from asphyxia. This is less frequently observable in pneumonia: the explanation appears to me to be this. In inflammation of the lungs, however, there may alter in texture, the bronchi are comparatively little affected: bronchial respiration, you know, is a common sign in the consolidation of pneumonia. In bronchitis, on the contrary, after the first turgescence of the membrane, comes a copious secretion, difficult of discharge, which fills the smaller ramifications of the bronchi: this is the occasion of the laboured respiration, and of the variety of sounds heard on auscultating the chest. If upon this comes congestion of the lungs, the air-cells get closed by pressure from the distended vessels, the expansion of the lungs is prevented, and the passage of air altogether denied through the thickened mucus of the bronchial tubes. Of course, suffocation is the speedy result of such a condition. I saw a case of this kind last year, in a bronchitic attack sequent of influenza. It was in the person of a dispensary patient, a female, about thirty-five years of age. She had been several days ill, and under the care of Mr. Carter, when I first saw her. I learned that her symptoms had been those of acute bronchitis in an urgent form. She had been judiciously bled two or three times; mild doses of mercury had been frequently given, and nauseating medicines at stated intervals. These not answering, a blister had been applied to the chest, and repeated. At the time of my first seeing her, she was breathing with great difficulty; at the lower part of each lung there was dullness on percussion, and respiration was inaudible superiorly, the stroke sound was not sufficiently expressed, and a loud mucous râle was everywhere distinct; cough frequent, and expectoration difficult; sputum opaque, tenacious, and in places slightly streaked with blood; pulse 112, feeble and fluttering; surface clammy; countenance anxious; lips livid; respiration short, quick, and laboured, and occasionally interrupted by a stifled sigh. It was evident in this case that, in spite of treatment, the congestion of the lungs and accumulation in the bronchi were increasing. Further depletion, of course, was out of the question. I advised a repetition of the blister, and prescribed ammonia, with squills, hyoscyanus, nitric ether, and camphor mixture; hot mustard and water to the feet, and mustard plasters to the calves of the legs. Still the chest symptoms increased, until respiration was reduced to a succession of gasps, and the face became almost purple, when death finally closed the painful process of slow suffocation.

In cases like these, depletory measures, local or general, are called for; proportioned, of course, to the strength of the patient and the severity of the attack. It is of much consequence to lessen the impulse of the circulation, but at the same time without unduly depressing the vital powers: if this latter occur, the chances are that your patient will sink. Of all modes of relief, however, none surpasses counter-irritant and derivative measures, and the promoting of expectoration. Free bronchial discharge is of cardinal consequence in the bronchitis. The fact, by no means novel, was well illustrated about a month ago, in the person of a gentleman residing in the country, whom I have been attending for some time past, in consultation with Mr. Chavasse.

this town. I was summoned hastily one evening to our patient. From a belief of his wife that he was dying. I found him sitting in an armchair, leaning slightly forward and gasping for breath. He put out his hand to me, but was unable to utter a word. His face was considerably swollen, eyes staring, lips purple, feet and hands quite cold and livid. There was striking pulsation and fullness of his jugulars, which I had never seen before. His pulse was 126, and very laboured; the stroke sound all over the chest was duller than natural, and the only respiratory sound was a loud mucous rattle audible everywhere. I learned that he had been sitting in a strong current of air for some time, until he felt a disagreeable chill, and that his present symptoms had shortly succeeded. It was quite clear that he was suffering from acute congestion of the lungs. An old heart affection under which he laboured utterly forbade bleeding, so I painted his chest plentifully with *aceticum lyticum*, but not until I had four times applied it abundantly did it make any impression. I immersed his legs and feet in very hot mustard and water, covered them well over, and then opened the door to allow him fresh air, for which he was panting in agony. This treatment was all very well, and perhaps I could not have improved upon it, considering the circumstances, but I should have had little hope of its efficacy, except for one striking feature in the attack—*copious expectoration*! So abundant was this, that at least half a pint of frothy, but still diffident, mucus was spat in an hour after my arrival. So long as this continued, I felt strong hope for the safety of my patient. I advised him to get the phlegm up as fast as he could, and the task at one time was a pretty constant one. At length the copious bronchial discharge, the counter-irritation, and the derivative action at the extremities, told salutarily, and the evidences of pulmonary engorgement began to disappear. I remained with him during the greater part of the night, and then left him in all respects comfortable and disposed for sleep. It was one of the worst cases of acute congestion of the lungs I ever saw; and, but for the discharge from the bronchi, would have soon ended, I have no doubt, in asphyxia. Beyond considerable weakness, and some increase of dropsical symptoms, with which he had often before been troubled, he has experienced no ill effects from his alarming attack.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILLSHIRE, M.D. (Edin.), M.B.S.,
Physician to the Royal Infirmary for Children, &c. &c.

(Continued from p. 179.)

GENTLEMEN,—In my last lecture I occupied your attention by directing it to the consideration of some of the more general relations of scrofulous inflammation and its results, &c.; and it will now be proper that I make a few observations on the other great sign of the general malady—namely, tuberculous deposit. I leave out of consideration for the moment, mind, what relation inflammation bears to tubercle, either as its cause or its effect: this I shall refer to afterwards. As I suppose you are all acquainted with the principles of general pathology, and have studied the general character of tubercle, I shall not detain you with any of the litigated points, as to whether grey granulation is or is not the first condition of tubercle, whether yellow tubercle first softens in the centre or the circumference, in what texture the latter is usually deposited, or like points. These subjects you will find discussed in most modern works upon general medicine; but I may, perhaps, direct your attention to the valuable periodical reports of Dr. Ranking, in which you will find everything you can wish.

Now, I may first tell you that as scrofulous inflammation may attack a child of any age, so may tubercle be deposited. There seems to be

no period of our existence quite free from the invasion of one or the other. It is true, as we advance beyond a certain point in age, we become less liable to the attacks of either of them, especially the former, as a primary disease, though not of the latter, but at an extreme limit. A fetus at birth has been seen to have tubercle in the lungs, and an adult at ninety-three years of age has been known to succumb to it.

A child may be brought to you evincing only some external form of scrofulous inflammation; it may have, for instance, conjunctivitis, or enlarged cervical glands, and yet be stout and active, and in other respects thought by its parents to be well. The artistic character also of the child may not either exemplify very strongly the scrofulous diathesis. In such a child there is no reason to believe that the other sign of scrofulous disorder—*tubercle*—has made its appearance. By careful attention to its *hygiene*, as growth progresses, you may preserve it a healthy child. But even in this child, let all the powers of life be brought to a low standard by bad food, bad air, deficient clothing, cold, wet, and like depressing circumstances, and tubercle is very likely to be *in futuro* generated. Not simply, mind, because bad food, bad air, and depressing mode of life will of themselves make a person scrofulous; but because here is a body with all the tendencies to the morbid deposit, and which will very soon yield to such exciting causes of its actual eruption. The finest constituted child, I believe, might be made tuberculous; but here you would have to make it so, and it might cost you some trouble. But in the other case it will demand equal care on your part that it may be preserved from it. Again, a child may be brought to you with enlarged glands, or conjunctivitis, but, instead of being active and well, it is quite the reverse—it is thin and not disposed to move much about; it pines away, the upper lip is very large and swollen—in fact all the *artistic* characters strongly marked; the fingers are clubbed, and the heads of the larger bones swollen; it coughs and perspires. In such a child as this, tubercle, in all probability, is deposited. Again, a child is brought to you without any of the common forms of external scrofulous inflammation, but it is very thin; hairy, as I before described, coughs much, and perspires abundantly; it may have *æthyma*—a very common thing in a coæthetic little patient; the fingers and bones are such as I just spoke of; it may eat even ravenously, the belly being greatly swollen. It will die, and tubercles will be found widely diffused over the body. A child makes no way from birth—it is a diminutive old man or woman in appearance; the bowels are constantly open; the *mraasmus* is extreme. The mother is a weak leuco-phlegmatic woman, has little milk; the father has died of phthisis, or the mother has suffered from syphilitic affection. The child soon dies, and tuberculous deposit will be found in its body. These are not imaginary examples I am giving you, nor pictures wrought up for the occasion; I have seen varieties of instances which may be ranked under one or other of these classes.

Children may be under treatment for month after month, year after year, for one form after another of scrofulous inflammation; and yet the *tendency*, the *inclination* only, to deposit tubercle be all this time apparent; children may at once, and at a very early age, be brought to you giving the signs of great diffusion of the deposit, and yet present no other inflammatory affections except such intercurrent ones as are caused by the *local irritation* of this peculiar morbid product.

Now, the product we are alluding to may be deposited or evolved in any organ, but still some organs are more liable to it than are others; and also, if it exist in some, it is almost always to be found in others in particular cases. You, perhaps, are not aware that there is a difference between its *distribution*, if I may so call it, in adult life, to that in infantile; but you may know that, as relates to the adult, it

has been said that tubercles are never developed in any organ after fifteen years of age, without being also developed in the lungs. Whether this really be the case or not, it is beyond my province to inquire; but I may tell you that Marsh, Churchill, and Bellingham do not confirm this axiom, and give instances of strumous peritonitis occurring in adults in which the lungs were quite free from tuberculous deposit. However, in children it is certainly the case that the lungs may be free from it although it is to be found in other localities. Still, in children the lungs are far more frequently affected than not, whenever the child is tuberculous; and many persons believe that these organs are the chief *nidus* for its evolution. A great law for you to remember with regard to children is, the *great diffusion of the deposit throughout the body*; and this, you know, is certainly not the case with adults. You may examine a child after death, and it will be one of the most astonishing things for you to behold how universally this product is deposited; and how the various organs are loaded with tubercle.

The spleen has astonished me, perhaps, more than any other organ. I have seen an entire mass of tuberculous matter of the densest kind. You will generally find that those organs which undergo tuberculosis more frequently, undergo it more abundantly and intensely too. Perhaps there is an exception to this, however, in the mesenteric glands and small intestines. In the former, very intense tuberculosis is not common, but of a moderate degree is more frequent than in the latter; whilst it is more intense in the latter, but certainly not so frequent. In children the bronchial glands play a very prominent part in the history of tubercle, and the coverings of the brain a very important and interesting one too. The heart is one of the organs of the body in children, as well as in adults, most unfrequently affected, and the stomach is very rarely so indeed. The peritonæum undergoes tuberculosis not unfrequently; and the false layers which are developed near it, and the intestines, may become charged with the deposit. In the liver it is not uncommonly met with; whilst, perhaps, you know it is rare there in adults, who, especially in France, have "fatty liver" instead. I do not know that I have ever seen the pancreas affected, but others have. The spleen, on the other hand, is very frequently in children loaded with tubercle, but its deposit in the kidneys is far less common. I have never seen it in the bladder or uterus, or in the ureters; others have. Nor have I seen it in children in the testicle, but still such cases are recorded to exist. Some persons also have found, they say, tuberculous deposit in the membrane of the tympanum, and suggest that from time to time it might be met with even in the membranes of the organ of vision. Of such extreme cases I can say nothing at all.

I have already told you it is not uncommon in the meninges, nor is it in the mass of the brain or cerebellum. The spinal cord has been seen attacked, especially the upper portion, by several observers. With regard to the bones—*deposit*, whatever it may be, is common, nay, constant, in their cancellated tissue on the occurrence of the "scrofulous disease of the joints." But still undoubted *tubercles* are admitted to occur in the osseous tissue, even by those who deny the "yellow lardaceous matter" to be identical with common tuberculous matter; but, then, such is rare. So is "cheesy matter" common enough in the lymphatic glands, and this, whether it be exactly the same as tubercle or not, is only common to scrofulous disorder. The sub-tentamentary cellular tissue also is a frequent place of evolution of the latter deposit. I think I have before remarked that "favus matter" is said by a good authority to be a modification of tubercle.

What I have now told you will sufficiently answer my purpose, I think, so far as relates to this portion of the history of tubercle as a great sign of scrofula; but as anything like an account of this portion of its pathology you must know it is meagre in the extreme, and gives you nothing

but the faintest outline of this vast subject. But these lectures, I told you, made no pretension to anything else but to be practical observations of a limited character. Still, for treatment you must have pathology, and before we get to the treatment of scrofula I must give you a little more. In doing so I must first touch upon one of the most litigated questions in the whole range of pathology, viz., is inflammation the cause of tubercle—is the deposit of this morbid product in any organ or tissue always preceded by inflammatory action there?

According to a great many pathologists this action is always a forerunner of the deposit of tubercle, whether this action be of the common kind or what others denominate low scrofulous inflammation; and some of them even go so far as to say that this action is sufficient to give rise to it without any pre-existing diseased state or abnormal condition of the blood, viewed as a general or constitutional affection. The opposite party deny this *in toto*, and assert that inflammation of any kind whatever has nothing to do with the production of the deposit, and that whenever—which is common enough—the effects of inflammation are seen in those organs in which tubercle is deposited, such effects are either the result of the local irritation of the deposit—and, therefore, to be regarded as produced by, instead of producing, the latter—or are, on the other hand, mere coincidences. It is an old axiom, you know, that between the extremes is found the truth; and I think such is the position in which you will here find it. These are pathologists who have assumed this position, and I believe it to be the truth. These pathologists believe that the deposition of tubercles may be, and often is, the immediate result of an action to which it would be absurd to give any other name than inflammation, but that there is, then, an essential peculiarity in the nature of the inflammation by which they are produced. But it is also the case, that as this morbid product is found in particular organs, as it were, indifferently—at least as regards its rapidity and extent of formation—under every variety of morbid agency to which these organs may have been subjected, we cannot believe that its immediate formation is *always* due to the previous occurrence of inflammation, and experience rather warrants us in maintaining that it is more often deposited without such inflammatory action having previously occurred. I cannot the extent of saying that inflammation is *never* really and truly the immediate local cause of tubercle being evolved. I cannot believe that wherever it is evolved there also has necessarily pre-existed, or is pre-existing, inflammation. You may depend upon it, a great deal of error in pathological reasoning, and of disagreement, has arisen from our not considering carefully and separately the nature of the aggregate phenomena implied, when we make use of the term *inflammation*. So long as we use—and surely it is permitted us at present by the language of pathology so to do—the terms of scrofulous, erythematous, rheumatic, syphilitic, chronic, acute, asthenic, asthenic, low, &c., inflammation—all terms implying some variation in the lesional, plastic, or symptomatic characters by which they are known—it is, as I have said, absurd to refuse the character of tubercular deposit also to be an attribute, mode, quality, element, or some other not infrequent and immediate connection, if you will, of an inflammation too. Or I may express it thus: we have strong reasons for maintaining, under the common acceptance of terms, and our mode of tracing causation and effect, that the deposit of tubercle must be allowed to enter into the series of aggregate phenomena by which inflammation under certain conditions of body is often made known. What I particularly wish to impress upon you is this, that inflammatory action may be, under particular circumstances, the immediate cause why tubercle is evolved; that in most cases, however, the deposit is not dependent on the pre-existence of this action; and that in all instances an abnormal condition of the blood plasma must first exist. In the greater number of cases tubercle is deposited as a subversion of

nutrition; in others, it is first induced to be deposited, if I may so term it, by local congestion or inflammation; whilst also its elements may be thrown out upon surfaces as simple exhalation. All these immediate local causes of its evolution may or may not be acting at the same time in the same body, and contiguous or not to each other.

Thus far I have thought it necessary, gentlemen, to carry you on in the pathology of tuberculous deposit; and I think this is quite far enough. At one time I had the idea of making these lectures more systematic than I now intend; and had drawn up for your notice the following table of phenomena, in their series of progressive occurrence, so that you might have a sort of bird's-eye view of what I believe to be the theory of the matter. I show it to you without making any remarks upon it, save that some chemists have lately held different views to what was promulgated upon the subject of *protein*. However, the table may be at least suggestive to you, if it is nothing else.

Scrofulous diathesis state of constitution of body.	Imperfect exhalation of chyle.	Blood unusually serous, poor in highly oxidized protein compounds, or having an excess of low oxydized ones.	Exudation from such blood of albuminous granular matter forms tubercle.

Exudations ensue in the processes of { Nutrition.
Inflammation.
Simple exhalation.

Exudation of the albumen and fibrine, or protein compounds, &c., ensues.

The albumen, fibrine, or protein compounds, &c., permeate the capillaries, and are imbibed by the tissues.

If the exudation be formed of the due proportion of elements, and is of right protein character, other circumstances also connected with assimilation being normal healthy plastic matter—new and proper tissue is the result.

If the constitutional tendency to make bad blood be great, the proportion of serum be high and constant, the diminution or highly oxydized protein, fibrine, and albumen great, the exudation is not able to form new tissue, a healthy plastic matter but remains as inorganizable granular matter—*tubercle*.

Exudations take place in inflammations.

On these taking place in many inflammations the lymph is organizable, diffused, exuded, is fibrinous, contains highly oxydized protein compounds, decolorized globules of blood, &c.

In inflammation of a scrofulous character the exudation is deficient in oxy-protein is incapable of acquiring vascular organization, does not form flakes or layers like those of other inflammations, &c.: in other words, inflammation very frequently causes an exudation of inorganizable albumen—*tubercle*.

Exudations from simple relaxation of solids and diseased states of the fluids may ensue.

In the healthy condition of the body peculiar properties of fibrine are necessary to retain the blood in the capillaries.

In the scrofulous diathesis the blood is poor in oxy-protein compounds, its motion languid in the small capillaries, and exudation of the albuminous, non-fibrinous, mal-oxy-proteinized granular matter is apt to ensue—*tubercle*.

From the above it may be deduced that—

1. The simple act of nutrition—at least an abnormal kind of one—may be sufficient for the deposition in organs of tubercle.

2. If the blood be very bad, and the constitutional tendency to form it so be very great, organic assimilation of any of the more important organs can scarcely be attempted in children

without being accompanied by tuberculous formation.

3. In a very great many cases not only is it unnecessary that inflammation should happen, but it is even not essential that any local congestion ensue for the deposit of tubercle to take place.

4. But in other cases it may be affirmed that, although the blood being bad, the scrofulous diathesis existing, the simple act of the nutrition of organs is not alone sufficient to give rise to the exudation of non-fibrinous inorganizable granular albumen in the form of tubercle. But ere, inflammatory action being superadded, or local congestion induced, the exudations are not a character with those of other inflammations, and tubercle is formed.

A COURSE OF LECTURES ON SURGERY, BY

SAMUEL COOPER, Esq., F.R.S.

Professor of Surgery to University College, London;
Consulting Surgeon to London University Hospital, &c.

LECTURE IV.

The first subject to which a student of surgery should pay especial attention is inflammation. It was a saying with the late Dr. Armstrong, that as soon as a student had obtained correct ideas of the nature of this affection, and made himself acquainted with the characters of some of the chief organic diseases, he might be said to have gained a bird's-eye view of disease in general.

When any part of the body is affected with redness, swelling, heat, and pain, it is said to be in a state of inflammation, implying by a figurative expression that the part is on fire, or seems to be so to the patient. Inflammation is naturally the first subject for consideration in a course of lectures on surgery, although it is one of the most difficult to understand fully and minutely. It forms, however, the key to the nature of other diseases: as it is connected with them as a cause, a symptom, an effect, or even as a means of cure, it may sometimes be considered rather as a salutary process than a disease.

I will first bring under your notice a few illustrations of the importance of inflammation as a mode of cure. We accomplish the radical cure of hydrocele by first evacuating the fluid contained in the tunica vaginalis, and afterwards exciting inflammation of that membrane by means of a stimulating injection, a seton, or some other means of producing inflammatory action. The effects of inflammation on the serous membrane is to cause an effusion of lymph, which obliterates the cavity in which the fluid had been previously effused. Encysted tumours or wens, and some other morbid growths, are cured by exciting strong inflammation in them, by the influence of which they are either slowly absorbed, ulcerate, or slough away. The effusion of lymph, as a consequence of inflammatory action, is necessary for the union of wounds without suppuration by adhesive inflammation—as we see in various autoplasmic operations—harelip for example.

Inflammation frequently exercises a salutary operation in the animal economy, by preventing evils which would be attended by serious or even fatal consequences. Thus it frequently increases the strength and thickness of serous membranes, when these are the only parts intervening between collections of matter and the great cavities of the thorax or abdomen, into which the pus would otherwise make its way, and occasion severe or fatal consequences. Inflammation, again, is of great importance in filling the cavities of the cellular tissue surrounding abscesses with lymph, and thus putting a stop to the spread of the matter, as would happen were such an obstacle not in existence. Again,

inflammation surrounds extraneous bodies lodged in different parts of the body with a sort of cyst, in which they may remain for a long period without injury to the system. In wounds of the bowels, again, inflammation plays an important part by preventing effusion of their contents, which would otherwise always follow wounds of these organs, and so bring on fatal inflammation of the peritoneum. This it does by gluing the wounded bowel to the neighbouring ones, or to the peritoneum at the edge of the wound, so that the fecal matters pass out through the wound instead of entering the cavity of the peritoneum. But inflammation can only be considered a salutary process when very moderate in degree, for where it attacks any part with great violence it is productive of the most disastrous consequences.

We have been accustomed to define inflammation as an increased action of the arteries accompanied by increased heat, swelling, pain, redness, and sometimes throbbing of the affected part. These are frequently accompanied by tension, induration, loss or diminution of transparency, alterations of colour, and other changes, which will come under our notice hereafter.

The term inflammation is often employed in a very vague manner, and without a precise notion of the meaning to be attached to it, either with regard to the symptoms which indicate its presence, or the local changes which are characteristic of it, or even of its intimate nature. Owing to these circumstances the distinguished French pathologist Andral would altogether reject the term as indicative of a complex process involving several others, the connection of which is by no means constant or necessary.

I am unable to give you an unexceptionable definition of the term inflammation. The expression, "increased action of the arteries," is much too vague when unaccompanied by any explanation of its meaning. I must defer the examination of this point until we have gone further into the subject.

Any one of the symptoms which I have noticed as indicative of inflammation may be absent, without our being able to say that the part is not inflamed. Thus, in the superficial inflammation of the skin, called erythema, there is no swelling, tension, or throbbing to be observed. In chronic inflammation, on the other hand, there is often considerable swelling, unaccompanied by heat, throbbing, or even pain and redness. Redness, although a common accompaniment of inflammation, is by no means one of its essential characters: for the vessels may not be so much dilated as to admit a large number of blood globules—as in inflammation of the arachnoid membrane, and slight inflammation of the cornea. The absence of redness is most common in chronic inflammations. Thus you will perceive that inflammation is a process liable to considerable varieties in its character, progress, and effects; and these variations are commonly dependent on the nature of the exciting cause, the state of the system, the patient's age, and the structure, situation, and functions of the part affected. The differences produced by the exciting cause may be illustrated by the influence exerted by morbid poisons on the character of the inflammation. Each morbid poison gives rise to a peculiar variety of inflammation of a specific character, regulated by certain laws, and having often a definite duration. Other examples may be found in the peculiarities of the inflammation, in the ulceration and gangrene of the fingers, toes, and other extreme parts of the body arising from exposure to cold. These peculiar forms require a treatment not at all suited to other forms of inflammation.

The influence of constitutional state in determining the kind of inflammation is well illustrated by scrofula, erysipelas, scurvy, and carbuncle. Inflammation is divided into acute and chronic; into healthy and unhealthy; into idiopathic and sympathetic; and into simple and complicated.

Acute inflammation is that form of the dis-

ease which produces all its effects with rapidity, which arises and runs its course, and terminates either in restoration to health or death of the patient, within a few days; if it produce an abscess, this occurs in an equally short space of time.

The varieties of acute inflammation are numerous, comprising not only all cases of healthy inflammation, but many other cases which may be considered as unhealthy and complicated.

Chronic inflammation is that which is slow in its progress, of a more or less indolent nature, accompanied frequently by little or no pain, or any perceptible increase in the heat of the part, and very commonly no redness. This form of inflammation often commences in a most insidious manner, so that its origin is completely overlooked. We refer to this chronic inflammation all those slow thickenings and alterations of various textures, and even the formation of several kinds of indolent tumours.

I am of opinion, however, that the doctrine is carried too far in the last instance, as it is extended to organic diseases and new formations, between which and the ordinary effects of chronic inflammation, the mere thickening of parts and their ulceration, there must exist very striking differences.

Scrofula affords us one of the most striking examples of the nature and consequences of chronic inflammation, as it is one of the most frequent diseases of our climate. Scrofulous inflammation is not, however, always of a chronic nature, for we see it occasionally assuming a very acute form, although it generally is of a chronic, indolent character.

Healthy inflammation is that form of the disease which is not modified by, or under the influence of, any particular disease in the system. Hence it does not show any of those peculiarities which we perceive in erysipelas, venereal disease, carbuncular inflammation, or that of cowpox, smallpox, or any other specific disease.

We commonly use the term phlegmon for healthy inflammation occurring near the surface of the body. Phlegmon has been defined as inflammation of the cellular tissue by some writers and lecturers; but it surely is not to be restricted to this tissue, as we see it involving the cutis, fascia, and other organs, which may be destroyed if the violence of the inflammation be great.

Unhealthy inflammation may be defined as that form of the disease whose appearance, progress, and termination are under the influence of some specific or determinate disease in the part affected or the system at large. The varieties of unhealthy inflammation are as numerous as the diseases which give rise to them. Thus we have scrofulous, gouty, venereal, rheumatic, scorbutic, erysipelatous, and carbuncular among the varieties of unhealthy inflammation.

Simple inflammation is inflammation of a healthy character, uncomplicated with any other mischief; which, for example, is not kept up by the lodgement of extraneous substances, or dead portions of bone, or surrounds cancerous or medullary tumours. When inflammation is accompanied or produced by such or analogous circumstances, it is said to be complicated.

When the causes of inflammation act directly on the part, the inflammation is said to be idiopathic or primary; but when it arises from disturbance in some other part of the system, or from any cause not acting immediately on the part affected, or preceding it, the inflammation is said to be sympathetic or secondary. These distinctions are of a practical character, and therefore of great importance, because the treatment of a secondary or sympathetic inflammation is essentially dependent on the removal of the primary disorder, which acts as an exciting cause, and is often remote in situation from the seat of the inflammation.

The terminations of inflammation, or, as it might be better expressed, the effects of this disease are—1. Adhesion of neighbouring parts to each other. 2. Suppuration, or formation of pus. 3. Ulceration, or the ab-

sorption and removal of portions of the tissue so as to leave an open chasm or broken surface which secretes pus. 4. Death of the parts called gangrene or mortification when attacking the soft parts, and caries or necrosis when destroying the bones.—Looking to these terminations or effects of inflammation, Mr. Hunter divided inflammation into adhesive, suppurative, ulcerative, and gangrenous, according as one or other of these results ensued; and he conducted his investigations in a careful, original, and philosophical manner, as you will perceive when you read his admirable work on Inflammation and Gunshot Wounds.

There is a remarkable tendency in certain cases of inflammation to one or other of these terminations or effects. The common phlegmonous inflammation and that of boils and whitlows has a great tendency to suppuration; that of carbuncles, the malignant pustule, some varieties of erysipelas, that arising from the animal poisons, and pricks in dissection, for its tendency to sloughing. Other forms of inflammation—that of mumps, gout, and rheumatism, for example—are never attended with suppuration, ulceration, or gangrene.

Much of the variety in the terminations of inflammation is dependent on the nature of the texture attacked by this affection, and its proximity to the surface of the body. Thus we observe that the inflammations of the cellular tissue, those of all the closed cavities of the body, of all deep-seated organs and serous membranes, are of the adhesive character, and are seldom attended with suppuration, ulceration, or sphacelus.

The mucous tissues, and those near the surface of the body, have a strong tendency to the suppurative form of inflammation. I may illustrate this by the progress of extraneous substances lodged in some deep-seated part towards the surface. While deeply lodged they do not cause the formation of pus, but as soon as they arrive near the skin suppuration is established, an abscess forms, is evacuated, and the foreign body finds an exit. Again, in gonorrhoea, we find that slight inflammatory action suffices to produce a discharge of pus, but intense inflammation is required to cause adhesions. The mucous membrane of the larynx and trachea, under ordinary circumstances, produces a purulent expectoration, while it requires the peculiar inflammation of croup to produce an exudation of lymph. You are not to expect that you will always, or even frequently, meet with these varieties of inflammation in their pure and separate state: for they are usually associated with each other in a greater or less degree, and are in this manner blended into one disease. Thus we have abscesses bounded by a layer of lymph, the product of the adhesive inflammation around their circumference.

In those tissues which are possessed of inferior vital powers, and comparatively ill supplied with vessels, ulceration and sloughing are the ordinary effects of inflammation. These results are seen in the sloughing of tendons and fascia; in caries and necrosis of bones; in the greater frequency of ulcers and sphacelus of the lower extremities than of the upper, which are nearer the centre of circulation; and in the greater readiness with which newly-formed parts ulcerate and slough when attacked by inflammation, than the original tissues; these, of course, possess a lower degree of vitality, and are, therefore, more obnoxious to injury by disease.

All inflammations of any extent or violence which attack important organs are attended by a disturbance of the whole system, to which the term sympathetic or symptomatic inflammatory fever is applied. In this constitutional affection we observe a frequent, strong, and full pulse; diminished and suppressed secretions; dryness and heat of the skin; parched and furred tongue and fauces, attended with extreme thirst; scanty and high-coloured urine; constipation of the bowels and anorexia, or absence of appetite for food. The nervous system partakes in the general disturbance: anxiety, restlessness, and sleeplessness, headache, subsultus tendinum, wanderings, and delirium, are among the symptoms referrible to disturbance of the nervous

system. The intensity and duration of the sympathetic fever are naturally modified by the violence of the inflammation, and its localization in parts which are of little or of great importance to life. When the inflammation has attacked an important organ, as in peritonitis, the pulse is quicker and smaller than when the skin, muscle, or other parts of smaller vital importance are attacked.

Differences of constitution exercise an important influence on the nature and extent of the symptomatic fever. When this rises to a great height, the pulse becomes more rapid and smaller, the brain is much more affected; and this is particularly the case in women and irritable subjects. You will find that fat and indolent persons bear inflammation very badly, and in them we frequently see the inflammatory fever very severe.

Persons who have ruddy cheeks, the redness terminating abruptly at its edges, and in which the minute vessels are seen to ramify, are commonly of a peculiarly irritable temperament, and bear inflammation worse than most others. In them the constitutional disturbance is extremely severe, and sometimes attended with spasmodic twitchings of the muscles, and imminent danger.

Diseases are not, however, restricted to changes in the solids; changes also occur in the fluids, and even the blood itself does not escape. The blood taken from a patient suffering from inflammation, coagulates more slowly and firmly than in its healthy condition; and, after the completion of the coagulation, you may observe a layer of fibrine of a yellowish or buff colour, or resembling glue, on the surface of the clot. The serum is usually more abundant. We call this yellow substance, the inflammatory crust or buffy coat. As a circumstance to which some importance is attached, it will deserve further consideration in a future lecture.

DUMAS ON ORGANIC CHEMISTRY. No. XIX.

ON THE BILE.
(Continued from page 192.)

Choleates.—Choleic acid unites with bases, and forms definite salts, some having neutral and others acid reactions. The neutral choleate of soda is the salt which constitutes the base of the bile. We may procure it directly, by purifying the bile by alcohol, animal charcoal, and ether; or else by a double decomposition, precipitating it by subacetate of lead, and treating the basic choleate of lead by carbonate of potass. In the dry state it forms an almost colourless gummy mass, which is soluble in water and in alcohol; its aqueous solution is distinguished from bile by one character only: the dilute mineral acids, when cold, separate it from the choleic acid, whilst bile is not precipitated under the same circumstances. If choleate of soda, dissolved in water, be treated by a concentrated aqueous solution of potass, this salt becomes separated under the form of a soap, and is found floating on the surface of the liquid.

MM. Theyer and Schlosser have analyzed this body, which they found composed of—

Carbon	60.14	60.12	59.60	59.16
Hydrogen	8.38	8.62	8.60	8.55
Nitrogen	3.75	3.32	3.30	
Oxygen	21.43	20.99	21.82	
Soda	6.30	6.95	6.68	6.11

Taking into account the chloride of sodium which the purified bile contains, we shall find it identical in composition with choleate of soda.

Choleic acid forms salts with an excess of acid; that which M. Berzelius called biliary substance, and afterwards bilifellie acid with an excess of biline, appears to be nothing more than the acid bilate of soda.

Oxide of lead forms two combinations with choleic acid; they are slightly soluble in water, and are dissolved by alcohol and acetic acid.

It may be obtained by precipitating a solution of neutral or ammoniacal choleate of soda by subacetate of lead. If we add nitrate of lead to a

solution of choleate of soda, a precipitate takes place. The supernatant liquor is neutral, or at least causes no effervescence with the carbonates (Demarçay). According to MM. Theyer and Schlosser, the choleate of lead contains—

Carbon	40.78	40.81	41.04
Hydrogen	5.92	5.98	5.81
Nitrogen	2.20	—	—
Oxygen	15.95	—	—
Oxide of lead	36.03	36.93	—

According to the same chemists, the basic choleate, prepared by rendering the choleate of soda alkaline by a little ammonia, contains—

Carbon	36.69	36.86	37.03
Hydrogen	5.16	5.38	5.24
Nitrogen	2.11	—	—
Oxygen	12.85	—	—
Oxide of lead	43.19	43.09	—

The neutral choleate of soda is changed into a basic salt by repeated washing.

Choleic acid is decomposed with great facility under the influence of various agents: the mineral acids and the alkalis transform it into new bodies. It is owing to these numerous modifications, that so many contradictory opinions have been formed as to the constitution of the bile. When treated by an excess of hydrochloric, sulphuric, or phosphoric acid, choleic acid becomes transformed into a peculiar body, devoid of nitrogen, which M. Demarçay has designated by the title of choloïdic acid, and into an azotized substance, named taurine, first discovered by M. L. Gmelin in the bile of the ox. MM. Theyer and Schlosser have observed that a concentrated solution of oxalic acid, whilst hot, effects the same transformation. If bile be thus treated, the acid seizes on the soda, sets the choleic acid at liberty, and transforms it into taurine and choloïdic acid.

Choloïdic Acid.—Biliary Resin (Gmelin).—This body may be prepared by dissolving one part of bile in five or six parts of hydrochloric acid of a mean strength; this solution is to be kept boiling for some time. The choloïdic acid separates from it in the form of a solid, brown, resinous-looking mass. The hydrochloric acid is removed by boiling water. To isolate the fatty matter, it must be dissolved in a little alcohol and subsequently agitated with ether. After separating the latter, the alcoholic solution is to be evaporated and the residue washed with water. It retains with great tenacity some traces of chloride of sodium.

Choloïdic acid is a fixed body, solid at the ordinary temperature; it is of a yellow colour, has a bitter taste, and is easily pulverizable. In the dry state, it melts at a temperature above 100° C. Heated in boiling water, it forms a brown glucy magma. It is almost insoluble in ether, but is dissolved by alcohol, even when dilute; it is slightly soluble in water. Its solutions reddens the vegetable colours and decompose the carbonates with effervescence. It forms salts which are partially soluble. Its composition is—

	Demarçay.		Dumas.
Carbon	73.62	73.30	73.16
Hydrogen	9.58	9.51	9.48
Oxygen	26.90	27.19	27.36

	Theyer and Schlosser.		Analysis.
C ⁶⁰	4551.24	72.53	72.23
H ¹⁰⁰	623.98	9.94	10.10
O ¹¹	1100.00	17.53	—

6275.22
To prepare the choloïdate of silver, MM. Theyer and Schlosser dissolve choloïdic acid in ammonia, boil the solution until it has become neutral, and precipitate it by nitrate of silver. It gives a voluminous white deposit, which becomes brown by desiccation. It contains:—

	Calculation.	Analysis.
C ⁶⁰	4551.24	52.77
H ¹⁰⁰	611.60	8.03
O ¹⁰	1000.00	13.13
AgO	1461.6	19.07
		19.35

The choloïdates of zinc, manganese, iron, lead, copper, and silver, are flaky precipitates, which, when heated with care, assume a grainy appearance and melt towards a temperature of 80° C.

M. Berzelius has given the name of *dyslysine* to a body produced by the imperfect action of hydrochloric acid on bile. If the resinoid substance, after being washed with water, be treated by alcohol of a specific gravity of 0.84, we shall find this menstruum take up two acid bodies which can with difficulty be separated one from another, and which the above chemist has denominated fellinic acid (*fellinsaur*) and cholinic acid (*cholinsaur*); there also remains a glutinous resinoid mass: this is *dyslysine*. This body is dissolved with difficulty, even in anhydrous boiling alcohol; on cooling, the alcohol becomes cloudy, and deposits, without growing clear, a white precipitate; by spontaneous evaporation, it is obtained as a white earthy mass. It is not dissolved by the alkaline carbonates.

By prolonging for some time the ebullition of concentrated hydrochloric acid on bile, diluted with a little water, MM. Theyer and Schlosser have obtained a resinous, yellow, perfectly neutral body, insoluble in water, alcohol, potass, acetic and hydrochloric acids, and which they regard as identical with *dyslysine*. It contains—

	Calculation.	Analysis.
C ⁶⁰	78.15	78.22
H ¹⁰⁰	9.95	9.68
O ⁷	12.02	—

Taurine.—Taurine was discovered by M. L. Gmelin; it is found in the mother-water left after the separation of choloïdic acid. The most simple process for its preparation, consists in boiling the bile with muriatic acid until the liquor, cloudy at first, becomes clear. The choloïdic acid is to be separated and the liquor evaporated until the greater part of its chloride of sodium is deposited. We then add to these mother-waters five or six times their volume of alcohol, and set the mixture aside. In a short time, the taurine will be found deposited as beautiful crystalline needles; these are to be washed in alcohol, redissolved and crystallized anew in water.

Pure taurine crystallizes in prisms having the form of a hexaëdron, terminated by four or by six sided pyramids. These crystals, which possess remarkable beauty, are hard, offer considerable resistance to the pressure of the tooth, and have a cool, fresh taste, which is neither saline nor sweet. Taurine exerts no action on the vegetable colours; it is soluble in fifteen and a half times its weight of water at 12° C.; in boiling water it is dissolved more readily. Alcohol takes it up very sparingly. Sulphuric and nitric acids dissolve it, without causing its decomposition, even at the boiling point.

At 100° C., these crystals lose nothing of their weight. At a more elevated temperature, they become inflated and turn brown, giving out an odour similar to that of indigo when burnt. Subjected to dry distillation, taurine furnishes a thick, brown, empyreumatic oil; we, moreover, obtain a small quantity of an aqueous liquid, of a sweetish and empyreumatic taste, which reddens litmus-paper, and sets free ammonia when treated by lime. This liquid gives a red colour to perchloride of iron.

The ancient analyses of taurine had led to the formula:—C⁸H¹⁴As²O¹⁰. But, M. Redtenbacher has recently found that this body contains 26 per cent. of sulphur. Combining this fact, therefore, with the analytical results of M. Demarçay, as well as those arrived at by myself, we find that taurine should be represented as follows:—C⁸H¹⁴As²S⁸O⁸.

Cholinic Acid (cholic acid of M. Demarçay; cholsaur of MM. Theyer and Schlosser).—Choleic acid is decomposed by the alkaline bases, as lime, baryta, strontia, oxide of lead, and even by its basic salts; these matters disengage from it nitrogen and hydrogen under the form of ammonia, and give birth to a new acid.

Cholinic acid was discovered by M. Demarçay. We must not confound it with the *chellan* acid of M. Berzelius, nor with the *cholic* acid of M. L. Gmelin. To prepare it, we melt one part of bile with two or three parts of hydrate of potass in a silver capsule, frequently adding to it small quantities of water, until all disengagement of

ammonia shall have ceased. We remove the excess of potash by a further addition of water, dissolve the soap which is formed by an excess of this liquid, and then add to it acetic acid. The solution, clear at first, becomes milky, and by repose there is separated a resinous, friable body, of a greyish-white colour, which quickly acquires a crystalline aspect in the water. We remove the precipitate, wash and digest it in ether, which readily dissolves the cholinic acid; then add a little alcohol to the ethereal solution, and abandon it to spontaneous evaporation. The cholinic acid is deposited in large transparent tetrahedrons, or in fine needle-shaped crystals, which are to be purified and rendered colourless by renewed crystallization. In the air, these crystals lose their transparency; they are soluble in alcohol and in ether, but very sparingly so in water. The solutions decompose the carbonates with effervescence, and possess a bitter taste. Heated in the air, cholinic acid takes fire and leaves behind an abundant residue of carbon. It is not volatile, and it gives by dry distillation products which have not yet been examined. It forms with the alkalis soluble salts, some of a neutral and others of an acid reaction; when combined with other bases, the resulting salts are but slightly soluble: they do not offer any fixed arrangement.

The following is its composition:—

	Thayer and Schlosser.	Dumas.
Carbon ..	70.10 70.07 70.23	70.36 68.5
Hydrogen ..	9.79 9.85 9.77	9.74 9.7

These analyses lead to the formula: $C_{40}H_{106}O_9$, which expresses the composition of the hydrated acid.

Cholic Acid.—This acid, which was discovered by M. L. Gmelin, is prepared by dissolving the precipitate, resulting from the reaction of subacetate of lead on bile, in acetic acid, and then decomposing by sulphuretted hydrogen; the sulphuret of lead is to be separated, and the liquid evaporated to dryness. We thus obtain fine needles of cholic acid, which are to be purified by further crystallization. By treating the sulphuret of lead by alcohol, precipitating the solution by water so as to separate the resinous part, filtering and evaporating, we obtain a fresh quantity of crystals.

Purified cholic acid is presented under the form of long, pointed crystals, which, when compressed between folds of silver paper, acquire a silken aspect. Its taste is both sweet and astringent at the same time. When heated, it melts into a brown oleaginous liquid, swells up, disengages an animal odour which quickly becomes aromatic, and burns with a fuliginous flame. Subjected to dry distillation, it furnishes ammonia: a sign which renders it impossible to confound this body with the cholic acid of M. Demarcay.

Water dissolves it but very sparingly, though more freely when hot than when cold. It is perfectly soluble in alcohol. Concentrated sulphuric acid also dissolves it, but it is precipitated from this solution by water. Nitric acid attacks it and decomposes it.

Cholic acid forms soluble salts with the alkalis. The solutions of nitrate of silver, nitrate of mercury, sulphate of copper, the perchlorides of tin and of iron, and also the neutral acetate of lead, are not precipitated by the solution of cholic acid; the basic acetate of lead renders it slightly cloudy.

M. Berzélius has given the names of *fellanic* and *cholanic* to two acids, which he states to have found in putrified and ammoniacal bile, after its being kept for a long time. Cholanolic acid appears to be identical with choloidic acid. Fellanic acid forms with baryta a salt slightly soluble in water, when cold; but if dissolved in boiling water or alcohol, it deposits itself on cooling under the form of colourless shining prisms.

Biliary Concretions.—The concretions which are found in the gall-bladder of man are formed, in most cases, of cholesterine, generally pure, but sometimes mixed with mucus, or with the colouring matter of the bile in a hardened state.

Some of these concretions have been found as big as a pigeon's egg. Where several of them exist at the same time, instead of possessing an ovoid figure, we find them flattened, and presenting the form of a polyhedron. Their colour and consistence vary: some have a dirty yellow tint; others are nearly white, and offer a crystalline fracture; sometimes they are brown, or of a brownish green, breaking readily, and appearing as an amorphous powder to the naked eye. Their density varies, according to their composition; the lighter kinds are the richest in cholesterine.

The following are some analyses of biliary calculi:—

	Glaube.	Brande.
Cholesterine ..	56 81.25	69.76 81.77
Biliary resin ..	8 3.12	5.60 3.83
Colouring matter ..	15 9.38	11.28 7.57
Coagulated albumen	9	—
Mucus	12 6.25	13.20 —
Soluble albumen, mucus, and salts ..	—	— 3.63

Biliary calculi are, in some rare cases, formed of mineral matters. We sometimes find in them the carbonates of lime and of magnesia. MM. Bally and Henry, jun., examined a calculus which presented the following composition:—

Carbonate of lime, with traces of carbonate of magnesia ..	72.70
Phosphate of lime ..	13.51
Mucus, colouring matters, oxide of iron	10.81

A black matter, resembling carbon, has also been found in some biliary calculi.

Bile of Animals.—Those chemists who have turned their attention to the composition of the bile have, in general, chosen that of the ox as the medium of their investigations. In fact, the data which we possess as to the nature of this liquid have served as a starting-point to all the researches which have been undertaken on the bile of other animals; and they have been applied in an especial manner to the study of the human bile, which it is more difficult to procure in large quantities.

Annexed are two quantitative analyses of the bile of the ox, performed by MM. Thenard and Berzélius. According to M. Thenard, 800 parts of this bile contain—

Water ..	700.0
Picro-nel ..	69.0
Fatty matters, partly acidified	—
Cholesterine (slight quantity)	15.0
Colouring matter (very little)	—
Yellow matter, arising from altered mucus (variable quantity) ..	—
Soda ..	—
Phosphate of soda ..	10.3
Chlorides of potassium and sodium	—
Sulphate of soda ..	—
Phosphates of lime and magnesia, with traces of iron ..	1.2
According to M. Berzélius, the bile of the ox contains—	—
Water ..	904.4
Biliary (and fatty) matters ..	80.0
Mucus ..	3.0
Animal matter, and chloride of sodium	7.4
Lactate of soda ..	4.1
Soda ..	—
Phosphates of soda and of lime ..	1.1
Trace of matter insoluble in alcohol	—
	1000.0

The analyses which have been performed on the bile of other animals have mostly led to some qualitative data, but which are altogether insufficient for the actual state of science.

The bile of the dog has been analyzed by M. L. Gmelin; it is thick, sometimes of a deep yellowish-brown colour, at other times of a brownish-green. It contains biliary sugar, a little biliary resin, much colouring matter, cholesterine, some salivary matter, mucus, an odorous principle, acetate, phosphate, and sulphate of soda, chloride of sodium, phosphate of lime, with margarate and oleate of potash.

M. Kemp has recently performed some comparative analyses of the human bile with that of

the ox, the tiger, and the leopard. The following are the results at which he has arrived:—

	Human bile.	Bile of the ox.	Bile of the tiger.	Bile of the leopard.
Soda	6.63	6.53	5.3	4.6
Chloride of sodium ..	1.87	0.37	—	—
		Bile of the ox.	Bile of the tiger.	Bile of the leopard.
Human bile.	I. II.	I. II.	I. II.	I. II.
Carbon ..	68.11 68.3	61.60 61.85	59.6	59.08 59.5
Hydrogen ..	10.13 10.0	9.62 9.10	11.8	9.19 10.0
Nitrogen ..	3.44 3.0	3.40 3.10	6.0	4.00 4.6
Oxygen ..	18.03 18.2	23.39 23.35	22.8	26.11 25.9

These figures are seen to differ remarkably from those which express the composition of hydrated cholic acid. They were obtained by deducting from the weight of the bile analyzed that of the soda and of the other solid materials, and they consequently express the composition of an anhydrous acid. It is, therefore, not surprising that the carbon should here be found in larger proportion than in the analyses of cholic acid, made by MM. Demarcay, Dumas, Thayer, and Schlosser. Moreover, the experiments of M. Kemp were often performed on quantities of matter much too small to enable us to accord to all his analyses a full degree of confidence.

ORIGINAL CONTRIBUTIONS.

OBSERVATIONS ON THE ACTION OF MERCURY IN INFLAMMATION, AND ITS EFFECTS ON THE SYSTEM.

By HENRY SMITH, M.R.C.S.,
Late House-Surgeon to King's College Hospital.

(Continued from page 173.)

Having considered, in my last paper, those evil effects which are most liable to arise from the use of mercury, namely, excessive salivation and purging, I shall proceed to speak of its administration, mentioning those forms of inflammation in which it is most chiefly useful, and the mode and form in which it should be employed.

Knowing the great power which mercury possesses in controlling some forms of inflammation, medical practitioners are, perhaps, too much in the habit of giving it indiscriminately, without sufficiently considering the locality of the disease, its nature, or the constitution of the person affected; and it is this fact that has, no doubt, brought some discredit upon the remedy, without its having really deserved it.

Before we use any powerful remedy, we should consider the disease for which we are going to employ it, and the effects which it usually produces on the system; if we have clear notions on these points we shall probably go on in as safe and clear a manner as our "conjectural art" will allow us.

Recollecting, then, that there are some forms of inflammation in which the nutritive function is chiefly deranged, and the constituents of the blood are thrown out in their most organized state; and that mercury has the power of altering the blood and changing the quality of those constituents which are thrown out as morbid products, we should suppose it was chiefly in such forms of inflammation that mercury would do most good; and so we find it. It is in inflammation of the solid organs of the body, and of the serous and fibrous membranes which envelop them and line the cavities in which they are placed, that this agent is so powerful, and its effects are so well observed.

In inflammation of the membranes of the brain, after general and local bloodletting has been used, and the bowels have been well purged, mercury should be given in quick and large doses, in order to get the system rapidly affected, as we know how rapidly morbid products form then, and what injurious results may take place, even should the patient recover from the present attack.

We sometimes see cases where inflammation is

suddenly lighted up in the brain and its membranes by the poison of syphilis. It is particularly in such cases as these that mercury is found to be so highly serviceable. Although the practitioner may be inclined to dispense with mercury in inflammatory attacks of the brain or its membranes, brought on by common exciting causes, yet, if he finds that the poison of syphilis has produced it, he has no other remedy to depend upon.

The practice of giving mercury indiscriminately in paralysis from affection of the brain is injudicious, and must be attended with bad results. In some cases when inflammation has preceded the paralysis, and there are indications of the existence of inflammatory softening going on, it may be proper to get the system under the influence of mercury; but we should always recollect that paralysis from affection of the brain indicates a loss of nutrition in that organ, and that mercury will only tend to increase this, and thus rather render the condition of the patient more serious.

In inflammation within the chest, mercury is perhaps more useful and more employed than in other parts. Here are situated organs which, when attacked with inflammation, are, from their texture, soon spoiled if the disease is not checked, and speedy means are not resorted to. Mercury, therefore, is so valuable. In pneumonia, the morbid products are quickly thrown out; there is a great increase of fibrine in the blood, and this is deposited in large quantities in the structure of the lungs, rendering the part of them impervious to air, and, if a sufficient quantity of the breathing apparatus is thus injured, death will soon ensue. We want some remedy to prevent this deposition of fibrine. We have it in mercury. Bloodletting and tartar emetic diminish the whole quantity of blood in the system, and relieve the engorged state of the lungs, in the earlier stage of the affection. Mercury, speedily and carefully given so as to affect the system, immediately after the bloodletting, or the first two or three doses of antimony, so alters the condition of the blood that the inflammatory process is checked, the fibrine is not deposited from the vessels, or, if it has been poured out, reabsorption takes place, and the lung is restored to its healthy state.

In some forms of pneumonia, bloodletting, and even tartar emetic in large doses, are not borne. Calomel and opium in moderate doses will be found effectual, especially if any parts of the lung have become solidified.

I allude to those cases in which the disease is produced by, or accompanies, some specific poison, as typhus fever, measles, inflammation of the veins, and erysipelas; at the same time that mercury is given, stimulants may without danger be employed.

In pleurisy, mercury is more generally employed than in inflammation of the substance of a lung; as a large quantity of lymph and serum is generally thrown out from this serous membrane, and their prevention and removal are considered to be the chief indications in the treatment of this disease. If the medicine is given at all it should be given at once (that is to say, after bloodletting, if that be deemed necessary), as the abnormal products are deposited rapidly and in enormous quantities from the inflamed pleura; and it must be admitted by all who have seen cases of acute pleurisy which have been followed by large accumulations of fluid, that mercury will sometimes have no effect in causing the removal of these, even should the system be well influenced by it.

The same remarks may be applied with regard to the pericardium when attacked with inflammation. It is undoubtedly a useful remedy in such cases if given early, before much has been thrown out; but if the physician waits until adhesion is beginning to take place between the two surfaces, or a large quantity of fluid has collected, the remedy which, if timely applied, would have assisted to prevent the mischief, will fail of doing any good; and that this is actually the case, I need only appeal to any of my readers

who have been in the habit of studying practical medicine in the right way, namely, by following his patient from the bedside to the dead-house: looking for the effects of his remedies not only in symptoms produced on the living body, but also in the signs which are presented to him after death. How often have they observed the sides of the pleura and pericardium joined together by recent lymph, their cavities filled with fluids, although the system may have been thoroughly brought under the influence of mercury!

If we look to the diseases in the abdomen, we again find that mercury is our most valuable therapeutical agent. The most formidable inflammatory attack man is exposed to is undoubtedly that in which the peritoneum is frequently involved: the extent of this membrane is so great that the most serious results are always to be anticipated; and the morbid products, as in pleurisy, are thrown out rapidly in large quantities, but particularly in that form of peritonitis to which puerperal women are liable. Mercury in these cases is our most useful agent. It was formerly the custom to employ general bloodletting to a large amount in these disorders; but it appears to be getting more out of fashion now, and practitioners mostly rely upon mercury and large doses of opium. The value of this combination cannot be too highly estimated in the treatment of these abdominal affections: the opium removes the pain and irritation, whilst the mercury prevents the deposition of lymph and serum by altering the condition of the blood. So much benefit results from this combination, that many persons are inclined to attribute the good to the opium alone, and to deny the principal power to the mercury. But it must be remembered that opium acts only upon one element engaged in the inflammatory process, namely, the nervous, and that it has very little power of controlling the disorder in the nutritive function; whilst mercury has no power over the former, but chiefly influences the latter. It would be folly to give the opium without the mercury, but a cruelty to give the mercury without the opium. Dr. Watson in his lecture on Peritonitis well says, "The opium is not to supersede the bleeding nor the mercury; it is not incompatible with either of the remedies; and it may, I believe, be most advantageously adopted in conjunction with them both."

There are many other inflammatory diseases in which the physician employs mercury, and which I have not mentioned; but before I leave the subject I must make a few remarks upon its use in the hands of the surgeon in one particular class of diseases, namely, in acute and chronic inflammation of the various joints.

When we come to consider the structure and functions of a joint: its great liability to inflammation, either traumatic or idiopathic; the rapid disorganization which ensues on such inflammation, if acute; and the more slow but not less certain spoliation, if chronic when we witness the lasting misery which is brought upon the poor sufferer from disease of particular joints, such as those of the hip or spine—we feel how necessary it is to use our utmost efforts to arrest the disease, and save the patient from the inglorious and unsatisfactory use of the knife, or from dragging on an unhappy existence; and, fortunately for our patients and our own reputation, conservative surgery is beginning to be generally cultivated, ay, even by those who previously shined in the use of the knife (as I can testify by the fact, that whilst conversing a short time ago, about a case of diseased joint, with one whose reputation needs no praise of mine, and whom I have many times assisted in the most severe and bloody operations of surgery, and whose coolness under the most embarrassing difficulties, and whose precision under favourable circumstances, I have so often admired; he made the remark, that "he hated to lose a limb"); and there is no doubt that many limbs, which would have been sacrificed a few years ago, can be saved by judicious treatment; and amongst the remedial measures, the employment of mercury stands prominent, and more particularly,

perhaps, in the chronic than in the acute diseases of joints. In acute inflammation of a joint, occasioned perhaps by a blow or puncture, the pain is so intense, the disease runs on so rapidly, and suppuration is so quickly produced, that the surgeon chiefly trusts to local measures applied vigorously and without delay, and these will frequently accomplish the object he has in view; but at the same time, if the disease does not appear to yield to these measures alone, and suppuration has not taken place, the system may at the same time be affected with mercury; and this will be found to assist much in overcoming the disease, and, with other judicious remedies it may prevent chronic inflammation from becoming persistent.

But it is in those cases of chronic inflammation of the synovial membrane that mercury cautiously given, together with other remedies, is very serviceable; and when we come to consider the nature of the changes which take place in a joint from this disease, we can readily understand how mercury proves useful. There is an increased secretion of synovial fluid, and effusion of lymph, and finally the membrane becomes thickened from abnormal deposits. Mercury will prevent this from taking place, and assist in restoring the injured joint to its proper function. If the inflammation in the joint has been the result of rheumatism, this remedy will be more particularly serviceable, and, if given early and carefully, may prevent the disease running on to a worse condition, which doubtless sometimes occurs after rheumatism, namely, ulceration of cartilages, and suppuration.

In those cases where we suspect incipient disease of the cartilages, produced either by chronic inflammation of the synovial membrane, or of the cancellated structure of the bone, and when the system has not been much depressed, and the powers of nutrition are not altered, the symptoms will be found to be alleviated by a judicious employment of mercury, and, if other suitable measures are followed, a complete restoration of the joint may be effected; but if the destruction of the cartilage is extensive (as we can ascertain by the grating sensation, and the distress of the patient at night), and the constitution has suffered much, it will be advisable to lay aside mercury altogether. It is, perhaps, a question as to whether mercury should be employed at all in scrofulous affections of the joints. When we come to consider the nature and pathology of scrofula—that it is essentially a disease of nutrition, that the products of scrofulous inflammation are of a totally different nature from those of inflammation excited by common cause, indicating a depressed and depraved condition of the nutritive powers—and, on the other hand, when we think of the effects which mercury produces on the blood and nutritive system, we shall find no difficulty in coming to a conclusion that this powerful mineral must be bad, and that the practitioner who employs it for the purpose of getting rid of the products of, and stopping, scrofulous inflammation, is not justified in his practice either by reason or sound pathology.

But, although the specific effect of mercury is hurtful in scrofula, there is no reason why it should be thrown aside altogether. We know that it benefits the body, by correcting certain depraved states of nutrition, when it is given in small doses as an alterative; and, as scrofula stands at the head of those morbid conditions, we may conjecture that the remedy will be beneficial here, and so undoubtedly it is: by exciting the whole glandular system, which is that mostly affected in scrofula, it proves useful when not carried too far; for to use the words of Brodie, whilst speaking of scrofula, "mercury used in large doses is invariably prejudicial."

Before I leave this part of my subject, I must say a few words on the beneficial effect which mercury possesses in some diseases of the spinal column. In those forms of disease where there is extreme pain and tenderness over a portion of the spine, and where it has not existed for any length of time, so as to produce suppuration,

but the symptoms clearly indicate the existence of chronic inflammation of the bones, or incipient ulceration of the intervertebral substances, mercury may be employed with a very good prospect of curing the disease. The product of inflammation in these cases is a large effusion of lymph which, pressing upon the nervous chords as they emerge from their canals, produces either partial

or total paralysis; and it is by preventing the too copious effusion of this substance that the benefit is produced; and even after palsy has existed there may be still a chance of a cure, as the mercury will cause the absorption of the lymph which has been already thrown out.

(To be continued.)

A NEW ARRANGEMENT OF THE BLOODVESSELS.

By JOHN JACKSON, Esq., Long Clawson, Melton Mowbray.

FIRST, OR

HEPATIC VASCULAR SYSTEM.

- 1.—*Hepatic Afferent Vessel.*—The Spleen, that is, its Venous Portion, and the Splenic and Portal Vein, and its ramifications in the liver.
- 2.—*Hepatic Capillaries.*—The minute bloodvessels intermediate between the terminal branches of the Hepatic Afferent Vessel, and the primary roots of the Hepatic Efferent Vessels.

- 3.—*Hepatic Efferent Vessels.*—The Hepatic Veins.

SECOND, OR

PULMONIC VASCULAR SYSTEM.

- 1.—*Pulmonic Afferent Vessel.*—The Right Auricle and Ventricle, and the Pulmonary Artery and its ramifications.
- 2.—*Pulmonic Capillaries.*—The minute bloodvessels intermediate between the terminal branches of the Pulmonic Afferent Vessel, and the primary roots of the Pulmonic Efferent Vessels.

- 3.—*Pulmonic Efferent Vessels.*—The Pulmonary Veins.

THIRD, OR

SYSTEMIC VASCULAR SYSTEM.

- 1.—*Systemic Afferent Vessel.*—The Left Auricle and Ventricle, and the Aorta and its ramifications.

—*Systemic Capillaries.*—The minute bloodvessels intermediate (1.) between the terminal branches of the splenic artery, and the primary roots of the Hepatic Afferent Vessel; and (2.) between the terminal branches of the hepatic artery, and the terminal branches of the Hepatic Afferent Vessel; and (3.) between the terminal branches of the Systemic Afferent Vessel generally, and the primary roots of the Systemic Efferent Vessels.

- 3.—*Systemic Efferent Vessels.*—(1.) the Gastro-Intestinal or Mesenteric Veins which terminate in the middle of the trunk of the Hepatic Afferent Vessel; and (2.) the Superior and Inferior Vena Cava and the Coronary Vein.

The Hepatic Afferent Vessel consists of a Spleen and Vein; the Pulmonic Afferent Vessel consists of a Heart and Artery; and the Systemic Afferent Vessel also consists of a Heart and Artery.

The Pulmonic Afferent Vessel causes a constant and rapid motion of the blood through the Pulmonic Capillaries; and the Systemic Afferent Vessel causes a constant and rapid motion of the blood through the Systemic Capillaries. What kind of motion of the blood does the Hepatic Afferent Vessel cause through the Hepatic Capillaries? It must cause some kind of motion. It can never be true that of the three Afferent Vessels two cause motion of blood and one not. Nor can it be true that an Afferent Vessel consisting of a Spleen and Vein can cause the same kind of motion of blood as an Afferent Vessel consisting of a Heart and Artery. If, then the Hepatic Afferent Vessel does propel the blood through the Hepatic Capillaries, and not, as is commonly supposed, the Systemic Afferent Vessel; and if it cannot cause either a constant or rapid motion, it must of necessity cause an intermittent and slow motion. The question, therefore, for physiologists to settle is, whether the Hepatic Afferent Vessel consisting of a Spleen and Vein is as perfectly adapted for effecting an intermittent and slow motion of the blood through the Hepatic Capillaries as either the Pulmonic or Systemic Afferent Vessel consisting of a Heart and Artery is for effecting a constant and rapid motion of the blood through the Pulmonic or Systemic Capillaries? If it is, the enigma is solved; and Heart and Spleen, and Artery and Vein, are anatomical antitheses.

But it may be said it is only the Venous Portion of the Spleen which is the roots or commencement of the Hepatic Afferent Vessel; what is the Splenic Artery for? And the Splenic Capillaries? The splenic artery, by dividing and subdividing, and ultimately splitting up into hair-like tubes or vessels, forms the splenic capillaries; and these splenic capillaries simply furnish points of origin for the roots of the Hepatic Afferent Vessel. These venous roots, the true spleen, could not originate from nothing; and, moreover, they could not originate from anything else than capillaries; and how could there be any splenic capillaries if there were no splenic artery? Venous roots only were wanted; but capillaries were necessary for them to originate from; and an artery was necessary out of which to make those capillaries. If there were

no splenic artery there could be no splenic capillaries; no splenic capillaries, no splenic veins; no splenic veins or spleen, no roots or commencement of the Hepatic Afferent Vessel; no roots or commencement, no trunk and no branches; no Hepatic Afferent Vessel, no Hepatic Vascular System; no Hepatic Vascular System, no Pulmonic Vascular System; no Pulmonic, no Systemic; no Vascular Systems, no motion of blood; no motion of blood, no life! See, then, the utility and importance of the splenic artery! From its capillary terminations springs the Hepatic Afferent Vessel, the first link in the great vascular chain! And why is it so large an artery? Because a large number of venous roots could not originate from a small number of capillaries, nor a large number of capillaries proceed from a small-sized artery. Why is it so tortuous? Why is not the splenic artery straight like the renal arteries? Because it is not the blood that is wanted, but the blood-vessel; and the tortuosity of the artery has the effect of minimising the quantity of blood that passes through it.

Intimately connected with the physiology of the Hepatic Afferent Vessel is the question, What becomes of the food eaten, and the fluids drunk, after they have been received by the alimentary tube? In other words, through what vessels, and into what vessel, do the fluids pass, and likewise the solids, after they have undergone fluidification or digestion? Are they both imbibed by the Gastro-Intestinal Capillaries, and then transmitted by the Gastro-Intestinal Veins into the middle of the Hepatic Afferent Vessel? Or are they both imbibed by the lacteals and transmitted by the thoracic duct into the left subclavian vein? Or do the fluids drunk take the former course, and the solids eaten the latter?

If, before birth, the Vessel which conveys the materials of nourishment and growth to the fetus, the Umbilical Vein, instead of going to the liver and terminating in the Hepatic Capillaries, like the permanent Hepatic Afferent Vessel, had gone behind the liver, and, like the thoracic duct, running along the spine, had ultimately terminated in the left subclavian vein; and if, in addition to this, the thoracic duct of the adult, instead of being so much less, had been very considerably larger, than the umbilical vein of the fetus, I would not then presume to call in question the truth of the prevailing opinion, that, after birth, the lacteals and thoracic

duct convey the materials of nourishment and growth from the alimentary tube into the left subclavian vein. But, as such is not the anatomical disposition of the umbilical vein and thoracic duct, I venture to take a totally different view. I maintain that the fluids drunk, and the solids eaten, (a) are both imbibed—the former rapidly, and the latter slowly—and not until they have become fluidified by the Gastro-Intestinal Capillaries; that they then pass through the Gastro-Intestinal Veins into the middle of the Hepatic Afferent Vessel; and that this vessel, being contractile as well as distensible throughout (i.e., in its roots, trunk, and branches), propels them with an intermittent and slow motion through the Hepatic Capillaries. I hold, therefore, that the materials of which the blood is formed, or, as I may now say, the blood itself, passes first through the Hepatic System; secondly, through the Pulmonic System; and thirdly, through the Systemic System. From the Systemic System a small portion finds its way back again into the Hepatic Afferent Vessel—that is, into its extreme roots by the splenic artery, into its extreme branches by the hepatic artery, and into the middle of its trunk by the gastro-intestinal veins; but by far the larger portion passes by the superior and inferior cava again into the Pulmonic Afferent Vessel, and so through the Pulmonic and Systemic Systems alternately, and for an indefinite number of times; that is, until its component particles are either deposited in some tissue, or eliminated in some secretion.

CASE OF SYPHILITIC INFLAMMATION OF THE UPPER EYELID—TOTAL DESTRUCTION OF THE TARSAL CARTILAGE BY ULCERATION.

By H. EVANS, Esq., Pwllheli, North Wales.

HISTORY.—An unmarried man, aged forty, had a foul ulcer, with inflamed elevated edges, along the lower margin of the right eyelid; the lid itself was very cedematous; the eyeball and its tissues undisturbed. It was then more than three months since its commencement; it began to show itself as a hard round swelling; he could not attribute it to any cause except having slept one night with the bedroom window open. He placed himself under the care of a surgeon, who scarified the palpebral conjunctiva, considering the case to be inflammation of the latter membrane. He was severely purged; and, not improving, the cedematous lid was leeches, and the temple cupped, and for some time took vegetable and mercurial tonics, being permitted also to have generous diet. No improvement taking place, he was ordered two grains of calomel with half a grain of opium, twice a day, and to persist in this treatment until the system was fully brought under its influence; to live well, and, in order to be able to form a better opinion of the effects of the mercurial treatment, to have no other local applications to the ulcer than water-dressing. The mercury was continued for six days, when profuse salivation was produced under this treatment; the burning pain, which he so much complained of, in the ulcer entirely left him, and the ulcer itself, instead of presenting the inflamed, raised, chapped margins described, presented characters totally different, so much so that, in three weeks from the date of his application, he was fit to follow his work as a joiner.

REMARKS.—The external characters of the ulcer, its suspicious situation, the man's age, and his previous dissipated habits—having been numberless times affected with syphilis, from which he never had been properly cured; the least exposure to wet and cold laying him up with pains in the bones, &c.; added to this, the knowledge of the fact that the general and local treatment to which he had been first submitted proving injurious rather than beneficial—left little if any doubt about the real nature of the complaint.

(a) These remarks, of course, apply to medicinal as well as to alimentary fluids and solids.

STRICTURE IN THE URETHRA.

There are circumstances which occur in stricture of the urethra from accident not mentioned by Sir B. Brodie, nor am I aware preceding authors having noticed them, viz., a flaccid state of the urethra anterior and posterior to the stricture, the anterior yielding upon slight pressure, forming a fold, carrying the bougie or sound, as it were, upon or over the stricture. The first case which came under my notice was in 1836, viz., James Abrey, aged twenty years, a seaman belonging to Sunderland, when in that harbour, fell from aloft and injured the perineum; he was attended by Mr. Crisp and a physician, at the time. After a few days, his ship being ready for sea, he was deemed sufficiently recovered to proceed in her. At this period there existed but slight difficulty in passing urine; this, however, daily increased, and when the ship arrived at her destination, St. Petersburg, after a passage of twenty-nine days, complete retention had taken place; he had not been able to void a drop of water for several hours. On his admission into hospital the bladder was distended above the pubes, and the slightest pressure caused increased agony; by bleeding, hot baths, leeches, opiates, &c., he was relieved of the urgent symptoms for a time, but no instrument could be made to dilate the stricture; and, after suffering nearly three months, passing much of his time upon his elbows and knees, straining to expel the contents of his bladder, it was considered advisable to cut through the stricture. The first steps as for lithotomy were proceeded with and, on bringing the urethra into view, the strictured part was obscured by the urethra above being greatly dilated, forming a pouch, protruding downwards and forwards, covering the stricture.—The second was John Klein, belonging to a Boston ship, U. S., who fell at sea, striking the perineum across the rigging; he was received into hospital thirty-four days after the accident, with hæmatocele and difficulty in voiding his urine; the hæmatocele was cured, and large bougies could be passed down to the obstruction, but, upon moderate pressure, the urethra was doubled over the stricture, whichever way the point was directed. This case progressed at the last, and was operated upon ere the patient had endured the severe and lengthened sufferings related in the first case. They both succeeded in every respect; but the pouch above the stricture in the latter was not larger than an acorn. The operation was not free from difficulty: in the first case the stricture was covered by the dilated urethra from above, which might have been, in some measure, obviated by a puncture, and letting out its contents; but the object was to effect a cure, and it was considered that a wound in the urethra so much enlarged would leave a troublesome, if not an incurable fistula: this was pushed backwards and upwards, and the stricture, which was of cartilaginous firmness, divided. In effecting this part of the operation, the most difficulty was experienced, and one not anticipated: from the commencement of the latter section the sound was useless, the fingers holding back the sac greatly obscured the sight, and when the hardened urethra was pressed upon by the knife, there was nothing to keep it from moving about in its connecting cellular membrane; this mobility caused nearly as much difficulty in the second case, and requires due consideration.

R. SOUTHER.

Cambridge, Jan., 1847.

WAR-OFFICE, April 30.—2nd Regiment of Life Guards: Surgeon Abraham James Nisbet Cornet, M.D., from half-pay 88th Foot, to be Surgeon, vice Calder, deceased.—To be Surgeon: Staff-Surgeon of the Second Class John Forrest, M.D., vice Hadaway, who exchanges.—Hospital Staff: Surgeon Samuel Maitland Hadaway, from 91st Foot, to be Staff-Surgeon of Second Class, vice Forrest, who exchanges.

PROGRESS OF MEDICAL SCIENCE.

France.

ACADEMY OF MEDICINE.

Meeting of April 20; M. BEGIN in the Chair.
INFLAMMATION OF FIBROUS STRUCTURES, BY
PROFESSOR GERDY.

The essayist began with remarking that in another publication he had already pointed out the close analogy which unites white tissues in general—such as the fibrous, cellular, synovial, and cutaneous structures. The influence of inflammation upon these structures was to indurate and shorten them; and this was the real cause of what was erroneously called muscular retraction, and more erroneously still treated always by tenotomy. Three cases were brought forward in support of this view. The first was one of contraction of the forearm, consequent upon diffused phlegmonous inflammation of the extremity; the skin was nowhere perforated, but its internal surface was ulcerated, and the dermis was reduced to a singular degree of thinness. The patient died from the progress of the acute disorder, and on dissection the anatomical cause of the contraction of the forearm was found to consist in the condensation of the cellular tissue, and the induration of the fibrous muscular attachments around the joint. The second case was one in which chronic inflammation of the knee-joint, complicated with caries of the tibia, had gradually brought on retraction of the limb. The synovial membrane and its fibrous lining, the cellular tissue of the neighbourhood, were thickened and indurated, without any alteration of the fleshy part of the muscles. In the third case, the cellular and fibrous textures of the temporal region had occasioned a considerable degree of stiffness in the movements of the jaw, and yielded to the beneficial application of poultices. These cases, said M. Gerdy, proved the hitherto-received opinion on the mechanical cause of contractions to be erroneous. Some years since, no surgeon attempted, for instance, to explain deviations of the spine—of club-foot, by the shortening of indurated fibrous tissue. When the question of tenotomy was agitated in 1842, before the academy, M. Gerdy alone defended this opinion; whereas it was generally contended that the cause of retraction was to be found in the fleshy parts of the muscles, and was most properly to be combated by section of their tendons. It was for this reason that in 1845 the essayist had read a paper on the retractions of white tissues, consequent upon inflammatory symptoms. This mechanism was the same in the strictures of the natural orifices and canals of the body, as it might be proved by reference to the anatomical alterations of strictures of the vagina, rectum, or urethra. It was true that in these parts another cause of retraction was also observed: M. Gerdy alluded to the deposition of morbid secretions around the diseased organs.

M. Bouvier agreed with all the opinions brought forward by Professor Gerdy except one: in the case of contraction of the knee-joint, M. Gerdy had said that the fleshy part of the muscles presented no modification of texture. Now, this was the case in every instance of retraction; it was absolutely impossible, on dissection, to detect in the muscles any anatomical appearances characteristic of the affection which had existed during life.

M. Blandin observed that the facts related by M. Gerdy fully demonstrated what it had been his intention to establish—namely, that the disease of fibrous textures might bring on deformation of the joints; but they went no further. They did not prove that prolonged muscular contraction could not have the same result. This state of things was not forcibly accompanied by a change of texture of the fleshy part of the muscles, but merely implied a diminution of their length—in a word, the disease was constituted by shortening, not by degeneration.

M. Gerdy insisted upon the frequency of anatomical changes in the fleshy portion of muscles

affected in this manner; he did not absolutely deny the existence of deformations caused by prolonged muscular contraction, but he asserted that they were very uncommon, and that generally their nature remained enveloped in considerable obscurity.—Meeting adjourned at five.

ACADEMY OF SCIENCES.

Annual Meeting of April 26.

M. Flourens read an historical *éloge* of Blumenbach, one of the eight foreign associates of the academy.

DISTRIBUTION OF PRIZES.

Experimental Physiology.—Gold medal, value £35, Mr. Bernard.

Physical Sciences.—M. Papenheim and Vogt.

Development of the Fetus.—MM. Baudrimont and Martin St. Ange.

Insalubrious Arts.—M. Laignel, £100.

Surgery.—£80 to M. Guillon, for the invention of a Lithoclast; £80 to M. Lucien Boyer, Researches on Strabismus.

Medicine.—£60 to Dr. Briere à Boismont, for his *Mémoire on the Treatment of the Acute Delirium Observed in Asylums for Insanity*; £20 to Dr. M. Lavallée, for a Paper on Cystitis caused by the Absorption of Cantharides; £20 to Dr. Maisonneuve, for his Experiments on Intestinal Inosculation.

HOPITAL BEAUJON.

CASE 1.—A workman was accidentally struck in the region of the sacrum with a hammer, and was immediately brought to the hospital. Abundant hemorrhage had taken place from the urethra; the blood was of a bright scarlet colour, and escaped in an intermittent stream, as if an artery had been divided. Compression of the perineum was unsuccessful in arresting the loss of blood, but the introduction of a catheter into the urethra at once stopped the hemorrhage. After five days the instrument was removed, and the hemorrhage recurred with the same violence as before. Again the introduction of a large catheter was resorted to; it has now been retained sixteen days, and the accidents have not reappeared.

CASE 2.—We recorded in a former communication (see page 97 of the present volume) a case presented to the Academy of Medicine by M. Hutin, surgeon of the Invalides, in which destruction of olfaction and of taste had been the result of adhesions of the soft palate to the posterior part of the pharynx. It was supposed by M. Hutin that the restoration of these two senses might follow the removal of these adhesions. A precisely similar case was recently admitted into the hospital by M. Robat, and the operation performed has produced the desired effect: olfaction and taste have returned, but the latter only imperfectly.

D. M'CARTHY, D.M.P.

EXTRACT OF A LECTURE ON PUNISHMENTS.

Delivered to the Students of Military Surgery in the University of Edinburgh.

By Sir GEORGE BAILLINGALL,
Regius Professor of Military Surgery.

There are general sentiments which I have expressed in this place for some years, upon corporal punishment, as regards the surgeon's duty in superintending its infliction, and in treating its consequences. If, upon the present occasion, I am induced to add anything of a more particular or personal character, it is from a desire to state fully and unequivocally the result of my individual experience as bearing upon a case which has recently been the subject of deep interest both to the profession and to the public. I allude to the case of Frederick White, of the 7th Hussars, who died, having been subjected to corporal punishment. Upon the medical evidence, I was induced to offer some remarks which called forth a reply from Mr. Erasmus Wilson. My opinion as to the soldier's death

is given in the following words:—"I can only look upon this as a case of thoracic inflammation, *superfening from atmospheric changes*, in the case of an individual who had recently been subjected to corporal punishment; except in so far that I hold every man who may have undergone such punishment, and who may in consequence be confined to hospital, to be in a condition which renders him more than usually susceptible of morbid influences, and particularly of those arising from atmospheric causes."

Here Mr. Wilson seems to think I have made an admission that this man's death was distinctly the consequence of his punishment. But observe, gentlemen, the words upon which I have laid an emphasis, and which I shall take the liberty of printing in italics. Observe also that a man is not of necessity confined to hospital because he may have undergone a slight punishment, not even such a punishment as that inflicted upon the soldier White; and which, in former times, would have been considered a moderate one. It is the assumed connection between punishment and pleurisy which I am disposed to question. It were altogether unfair to take Mr. Wilson's evidence as given in the newspaper reports, or to say how far some of the expressions put into his mouth countenance the parallel which has been drawn between the effects of burns and of corporal punishment; but he is well aware of the relation which exists "between the skin and the internal organs," and how much this relation has been dwelt upon, as explaining the fatal result in the present case. Mr. Wilson's own explanation of this result is distinctly given in the following words:—"The pulpy condition of the muscles existing in close relation with the pleura, was the real cause of the pleuritis which was found on that side of the chest."

Now, it is the immediate connection of the fatal pleuritis, either with the state of the skin or with the state of the muscles, which, in my opinion, remains to be proved. If this is not the professional question at issue, I should be glad to know what that question is. And why this persevering attempt to ascribe to a peculiar—I had almost said a nondescript—state of the muscles of the back, those morbid appearances which the thorax, which are abundantly common where no such cause can exist? The concatenation of extraneous or accessory circumstances in this case—the soldier's trial, his punishment, his reception into the regimental hospital, the healing of his back, his subsequent death, and repeated dissections—have never been denied.

Mr. Wilson then places me hypothetically before the coroner, and, after having delivered my opinion as formerly expressed, supposes the following question to have been asked of me:—"If the deceased had not been flogged, would he in your opinion have been alive at the present time?" To this I should at once have answered, "I can give no opinion on the subject. I cannot tell." A coroner's inquest is to me by no means so novel a scene as may be supposed. I have been repeatedly a witness before that officer, and have never met with anything in the least degree puzzling or unpleasant; which I attribute to my having uniformly adhered to the following simple rules: to make my answers as brief and concise as possible; to avoid any "medical dissertations on the relative dependencies of predisposing, exciting, or proximate causes;" to abide rigidly by the dictates of "common sense," and to eschew all professional refinements into which it were impossible for a jury to follow me.

Mr. Wilson, in the course of his reply, enters again upon ground over which I have already professed my inability to follow him—the softening (ramollissement) of the brain. The latter is an affection with which we are all familiar; the former is to me altogether unknown. I have no inclination and no title to deny its existence, but I am entitled to say that after a period of upwards of forty years' service in hospitals, civil and military, I have never

seen, and, until within these few months, never heard of, such a morbid affection. I regret that the knowledge of such a degeneration of the muscular tissue has come upon me at a late period of life, when many valuable opportunities of investigating its nature have passed away; and when the state of my eyesight, independently of other considerations, renders it now impossible for me to pursue with any advantage the "slim unravellings of minute anatomy." I have repeatedly seen the superficial muscles of the back twittering under the lash, and I know something of the rupture of the long muscles of the extremities; but I have a difficulty in conceiving how a muscle like the multifidus spinæ, peculiar in its structure, thickly covered by the superincumbent parts, and limited in its range of action, should be so powerfully affected as to lead to its rupture and subsequent degeneration. And here an important practical question presents itself. In cases of severe contusion it is not unfrequent for suppuration, and even sloughing, to go on in deep-seated parts, while the texture of the skin remains unbroken. But in a complicated injury of the superficial parts like that from flogging, consisting of laceration, contusion, and extravasation of blood, is it usual, or is it known, that such superficial parts recover themselves, and that this recovery goes on to a complete cicatrization of the skin, while such a morbid process as that described by Mr. Wilson is going on below?

In opposition to my opinion of the infrequent connection of corporal punishment, as inflicted in our army, with inflammation of the thorax, and in reply to my repeated demand for evidence of such connection, I am referred to the testimony of Lord Hardinge, the present Governor-General of India; to that of Kirckhoff, formerly a physician in the army of the Netherlands; and to the memorable case of Sergeant Armstrong, as supporting Mr. Wilson's belief "that diseases of the thoracic viscera are far from being an uncommon result of corporal punishment." It so happens that there is not a man in the British army, from right to left, for whom I entertain a more sincere respect than for Lord Hardinge, but upon a matter of professional opinion I shall not be expected to yield my judgment even to the matured experience of his lordship. But is Lord Hardinge's evidence upon this subject fully and fairly represented? I have looked over the "Blue Book" containing the "Report of the Commissioners for inquiring into the System of Military Punishments in the Army," and there I find the following questions submitted to Major-General Sir Henry Hardinge, with the replies respectively annexed to them:—

"5656. Are you at all acquainted with the discipline of any of the other armies of Europe, from having served with them?"

"No, except of the Portuguese army, of which I was the Deputy Quarter-Master-General from 1809 to 1813.

"5657. In the Portuguese army there are very severe punishments by strokes of the sword:

"Having commanded five battalions of Portuguese in the Pyrenees, the result of my observation is, that the soldier, from his nature and character, is not so difficult to manage as the British soldier, and principally because he is much more sober than the British soldier; he has less personal resolution to resist authority; more submission from his previous habits as a peasant. Punishment was inflicted by a corporal seizing the culprit, and striking him with the flat of the sword upon the back. It was necessary to be done with the utmost caution, for it shook the chest so severely that sometimes consumption and lingering complaints were the consequence.

"5658. It did not leave any mark?"

"No, it bruised the body, and frequently led to spitting of blood and very serious complaints; and it was not calculated to have the same effect of deterring from crime that our system has, because being given with the clothes on, and the man not appearing to suffer much from it, if he had the resolution to conceal his suffering, which

many firm men have, it had not the effect which our punishment has of deterring by the appearance of a more severe punishment."

Here it will be observed that Lord Hardinge is contrasting, morally and physically, two punishments of a very different description—that of the forcible blows with the flat of the sabre, as practised in the continental armies, with the cat-o'-nine-tails as employed in our own. It is of the former alone that the spitting of blood is said to be an occasional consequence; and this is an event which I confidently affirm that I have never observed as a sequel of the most severe punishments as inflicted in our service.

For the authority of Kirckhoff, to whom I had occasion to refer in the introductory part of the course, you are aware that I entertain all possible respect when treating of subjects with which he is personally conversant. He speaks of the "coup de baton" as productive of hæmoptysis; but in reference to corporal punishments, as inflicted in our army, his authority must go for very little. Upon the latter subject he could have had little if any experience, infinitely less than what Lord Hardinge has had of the "coup de plat de sabre;" and no one who has had an opportunity of seeing the two punishments inflicted will, for a moment, look upon them as likely to be productive of the same results.

Of the case of Sergeant Armstrong, whose life was sacrificed to the violence of his commanding officer, Governor Wall, I am not at the present moment in possession of any perfect detail. He is said to have passed blood constantly after his punishment, both by urine and by stool; and the surgeon stated also that he had an asthma from the extraordinary absorption of the blood. It is altogether unnecessary for my present purpose to inquire how far "the flogging occasioned disease of his lungs," as stated by Mr. Wilson, because, if my memory serves me, Sergeant Armstrong was said to have been punished with a rope an inch in diameter. If this is correctly stated, it will be seen at once how completely it takes the case out of the category of punishments as usually inflicted in the British service, and how far it assimilates this case to those punishments spoken of by Lord Hardinge and by Kirckhoff.

I have now disposed of all the evidence adduced in support of Mr. Wilson's position; and of the several analogies brought forward in illustration of the views of those from whom I differ as to the nature of White's case, it will be observed that there is not one of them which I can admit. The parallel between burns and flogging I stated, in my former paper, to have been, in my opinion, "pushed much too far;" the parallel between the ramollissement of the brain and a correspondent state of the muscular tissue is a point upon which I am unable to speak; and anything like a parallel between the punishment with the flat of the sabre, or with "a rope an inch in diameter" and the cat-o'-nine-tails, I altogether deny.

I come next to what was the principal object of my former communication, and what now becomes to me the most important object of this, the statement of my personal experience. Upon this, Mr. Wilson observes, "Sir George Ballingall's assertion, that in the two hundred cases above referred to there had not been any prominent or dangerous symptoms of thoracic inflammation, is most disagreeably qualified by the adjectives prominent and dangerous." Now, I beg to assure Mr. Wilson that in making the above statement, I had no equivocation nor mental reservation in view, and that I had studiously and purposely understated both the extent and the result of my experience, as bearing on the question at issue. Mr. Wilson goes on to ask, "What was the proportion of thoracic disease of whatever kind? For what period after punishment were these men observed? Might they not, months after, nay, perhaps years, have languished with disease of the thoracic viscera, the seeds of which had been sown by the punishment to which they had been subjected?"

These are most proper, most pertinent, and most legitimate questions; and it is to me a source of regret that I am unable to give a more direct and specific answer. I can only state generally that I have served in four different battalions, and in three different quarters of the world. I was painfully reminded by an old brother officer, a few days ago, that there can be but few men living who have seen more corporal punishment than I have, or under a greater variety of circumstances. I have seen such punishments inflicted, both at sea and on shore, in the field and in quarters, in the cold of a severe English winter, and under the heat of a tropical sun. I have seen them inflicted by the powerful arm of a bontswain's mate, and by the tiny hand of a puny drummer, the number of lashes varying from one dozen with the heavy naval cat to six hundred with the less formidable instrument used in the army; both of which are now in your hands. And, in reply to Mr. Wilson's questions, I can only say that in all this variety of circumstances, I have not only seen no "prominent or dangerous symptoms of thoracic inflammation," but, so far as my recollection serves me, I have seen no such symptoms whatever. I say this with all the increased confidence which further reflection gives me; and I repeat that in no case under my own care has there been a direct or obvious connection between punishment and pleurisy or carditis. There was no such connection as to induce any soldier to attribute the occurrence of such diseases to a preceding punishment, so long as I remained in the regiment with him.

The mode of dressing punished men's backs, in this and other cold climates, during the war—a practice still in use—appears to me a very powerful argument against anything like a general or frequent connection between punishment and pleurisy. This dressing consisted of a solution of the acetate of lead, with which the contused or broken surface was kept continually wet, by means of a pledget of cloth or charpie soaked in the solution; the patient's body linen, his sheets and bedding, being not unfrequently imbued with moisture; and this at all periods of the year.

In a matter of this grave importance, upon which I have expressed myself so strongly, it is a great comfort to know that my experience is by no means singular or isolated. I have looked into all the cases mentioned in Mr. Marshall's recent work on military punishments. I have looked into those detailed in "Hamilton's Regimental Surgeon," into a few that are noticed in the periodicals, medical or military, and into some manuscript cases in my own possession; and, singular as it may be, it does not appear in any of those cases that life was either lost or endangered from the supervision of acute thoracic disease.

I have also been favoured in the course of the bygone winter with a voluntary and unsolicited statement of the experience of five medical officers of long standing in the public service, three of them holding the rank of inspectors of hospitals, and all assuring me that their observation is coincident with my own. The dangers have been, as formerly stated, from "profuse suppuration, sloughing, or hospital gangrene;" or, as Mr. Marshall has expressed it, "fever and sloughing of the back are the consequences of flogging most to be dreaded."

Fatal cases of acute inflammation within the chest from atmospheric changes (and to which men depressed and debilitated by confinement to hospital are particularly obnoxious) are, in this country, cases of every-day occurrence; while, on the other hand, I trust I have been able to show that such complaints as a consequence of punishment are, in our service, exceedingly rare, if not altogether unknown. That White's case was an example of the more frequent, not of the more rare, occurrence, I am firmly persuaded; and I am bound to conclude that the only one of the five medical gentlemen examined in the case who entertains an opposite opinion is equally sincere in his belief. Had

any doubt existed in his mind, I must presume that he would have given to the surgeon more immediately concerned the benefit of that doubt. That he would have been slow to lend the weight of his testimony to the support of those who had evidently prejudged the question, while, on the other hand, that testimony was calculated to injure the character of a professional brother, to impair his usefulness, to expose him to public odium, and to destroy his peace of mind.

I would, gentlemen, most willingly forego the necessity of coming again before the public, in reference to the case upon which I have just been commenting. For professional controversies I have ever entertained but little respect, and the tardiness of my reply upon the present occasion will, I trust, be admitted as some indication of the little taste I have for what frequently proves a most unprofitable waste of time. There are circumstances also in the present case which render any protracted discussion of it to me more than ordinarily disagreeable. I have found from experience, that it is difficult, in the eyes of many, to controvert the professional opinions of the coroner and Mr. Wilson, without being at the same time supposed to counteract their praise-worthy object.

Upon the propriety of abolishing corporal punishment in the army and navy I have never permitted myself to enlarge in this place, being of opinion that it is a question not within my province; but I have elsewhere stated, many years ago, the result of my professional experience as to the unequal operation of this punishment on different individuals; and I have stated a fact which ought never to be absent from your recollection—that those who most deserve this punishment are often the least able to bear it. Trusting then to these statements for the vindication of my humanity, I go on to observe, that if I can hope to be of any use to you, it is by the accuracy of the professional opinions which I may deliver from this chair, and by being always prepared to defend them. I feel, at the same time, that I am not entitled to take advantage of my position here, to say anything to you which I am not prepared to say to the public. It is not then in the spirit of controversy, nor is it for the purpose of qualifying or retracting one syllable of any former statement, that I again resort to the press. No, gentlemen, it is from a desire to repel something like an insinuation of mala fides that I have been thus pithy and thus egotistical. If there is anything for which I have obtained or desired to obtain credit, in my intercourse with my pupils, it is for a candid statement of the results of my experience, and I am not willing to forego any character I may possess in this respect, now that I am looking forward to the termination of my professional life.

Incision of the Os Uteri in Obstructive Dysmenorrhœa.—Dr. Simpson has been in the habit, for the last three or four years, of performing this operation in cases of obstructive dysmenorrhœa. He thinks that the sufferings in this complaint arise from the uterus being driven into contractions to expel retained menstrial secretions, and that the retention arises from a want of relation between the quantity of fluid secreted and the quantity allowed to escape. The instrument which the doctor uses is a kind of lithotome caché. The end of the instrument is passed up through the cavity of the cervix, and within the os extermum. It is then slightly opened laterally, first on one side and then on the other, so as to divide any fibres that may be causing constriction of the internal orifice. The principal incision is then made in withdrawing the instrument. This incision commences at the union of the cervix with the body of the uterus, and passing gradually more and more into the substance of the cervix as it descends, the blade is brought out at the outer and lower edge of the cervix, at the point of reflection of the mucous membrane upon the wall of the vagina. The instrument is then turned, and a similar cut

made on the other side. Care must be taken that it does not pass beyond the substance of the cervix, as it is closely surrounded by a plexus of veins. The operation causes but little pain, and the hemorrhage is usually very trifling. If there is a tendency in the lips of the wound to cohere, they must be touched two or three times with nitrate of silver.

Ringworm treated by the Application of Blisters.—Dr. Maclellan has found that this troublesome disease, when it exists on the scalp in one or two detached spots, or when it appears on the face, neck, or arms, may, if taken in time, generally be cured in a few days, and prevented from spreading, by blistering the surface thoroughly, and dressing the blisters with cotton. The blister must be a little larger than the affected spot, and it will be found to be more manageable than the caustics frequently used.

Mode of detecting Sugar in the Urine.—In the hospital wards of Paris the following method is adopted:—Place in a small tube two drachms of urine, add half the quantity of liq. potassæ, and boil for one or two minutes. If the urine contain sugar, it will assume an orange brown or lustre tint. If there be no sugar present, it will become paler on ebullition. All that is necessary for this operation is a small tube, a little bottle containing potash, and a spirit-lamp.

Typhoid Fever.—M. Rayer has used tepid baths daily with considerable success in the treatment of this disease. The pulse loses its frequency, the heat diminishes, the tongue becomes cleaner, and the head feels clear under this treatment.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsman or Bookseller, or it will be sent direct from the Office of the Medical Times to Annual Subscribers sending by a Post-office order, directed James Angerstein Carey, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

A HANDSOME PORTFOLIO for holding the "MEDICAL TIMES"—very desirable to those who would keep the numbers clean for binding, and easy of reference—may be had, by order of any Bookseller, or at the Office, price 6s. An allowance is made to the trade.

Ignoramus. To apply a bandage well requires practice; and patients judge of the skill of their medical attendants by their dexterity in little things.

Mr. Horace Wells, of Hartford, U.S., has forwarded to us a pamphlet, addressed to the European and American public, in which he brings forth many documents, signed by most respectable individuals, professional and non-professional, to show that in November, 1841—nearly two years before Drs. Jackson and Morton—he had used and had made known the effects of nitrous oxide gas, and ether, in rendering persons insensible to pain.

I. A. C. Stroud.—A licentiate of the Apothecaries' Company will be admitted to examination for the diploma of a licentiate of the Royal College of Physicians, London, when he is forty years of age, and having been in practice a certain time.

J. Turnbull.—The suggestion shall receive our best consideration.

Caustic is too strong for our pages.

Mr. Goulding's letter did not reach us. We cannot account for the cause.

The indignation of an Old Surgeon is just. He need have no fears about the bill.

Rusticus may use the article in question in any way he pleases. Its publication may be of use.

Permissus extra Urbem.—The College is in a quandary. It is likely the rulers will offer no very determined opposition to the new charter of incorporation of general practitioners, from a desire to get something themselves.

A Reporter is requested to communicate his name in strict confidence.

Senax and an Army Surgeon, on the recent application of Dr. Warren, have been received and are under consideration. We cannot publish the letter of "Vindictor" on the same subject, without entering ourselves on the merits of the whole matter—a task we are not desirous of seeking.

M. D. is informed that we shall early give attention to the facts he forwards.

A General Practitioner near Manchester says—"I regret there is not a medical agent for you Manchester; I am sure one there would make an excellent thing of it. If a communication is made in your valuable periodical it may be a means of bringing some one."

M.D., M.R.C.S.E., Ashton-under-Lane.—The articles you name being charged in a bill may, we think, be recovered by action at law.

The Rev. Charles Chambers, Ampthorp Vicarage, Andover.—The lectures are not yet published, but will be very shortly. The request shall be attended to.

Dr. Barker's case has been received.

T. E. Jamieson.—A five years' apprenticeship cannot at present be dispensed with if the license of the Company is afterwards to be obtained.

Inquirer.—The Poor-Law Commissioners can put a veto on the election of a surgeon by a board of guardians if he does not possess the double qualification.

Justitia very justly complains of the many defects in the bill. Nobody imagines that it has been introduced into the house with a view to passing. Parties are wide awake.

A. B. C. informs us that No. 277 in the exhibition of the Royal Academy is no other than Professor Hollar's. The picture must be well worth seeing.

E. A., Bury, can obtain every information in the Army or Navy Lists.

Mr. H. B. Norman.—The account of the testimonial lately presented to Dr. Taylor, late professor of clinical medicine in University College, has been received, and will be noticed next week.

We have received communications and letters from Mr. Doyle, Liverpool; Dr. Roe, Curran; Mr. Brownlow, Banbridge; Dr. Curran, Dublin; Dr. Vallack, Ventnor; Mr. Cass, Cores; Mr. Rutherford, Rothbury; Mr. Boulton, Usk; Mr. Hay, Portsmouth; Mr. Fallon, Liverpool; Mr. Broughton, Ruyton; Mr. Cartwright, Teignmouth; Mr. Foster, Tadmorden; Dr. Minchin, Dublin; Dr. Price, Waterford; Dr. Seward, Cahircinlish; Mr. Dalley, Markfield; Mr. Hopper, Rotherham; Mr. Smith, Belper; Mr. J. H. Smith; Mr. Evans, Porthell, North Wales; A Constant Reader; A Candidate, Grosvenor-square, Manchester; Mr. Chamberlain, Canab; J. B., Beccles, Mr. Bridge, Paul Prep, A Student of Charing-cross Hospital.

Notices of several schools, including St. Bartholomew's, must stand over till our next number.

THE MEDICAL TIMES.

SATURDAY, MAY 8, 1847.

THE MEDICAL REGISTRATION BILL.

THE coroner-member for Finsbury has again bid for professional support, by the introduction into the House of Commons of an old Registration Bill with new dressings, an abstract of which, divested of technicalities, will be found in another part of our columns. We have given it for the inspection of the profession, that the members may look at it carefully, intelligently, and thoughtfully, remembering that they are the parties for whose benefit, ostensibly, it is intended, and that future honourable prosperity is closely connected with the stability or destruction of this bill. There can be no dispute about the necessity of legislating for medical men as speedily as possible, in order that they may be placed in that honourable station to which their education en-

titles them, and that they may be eminently efficient as conservators of the public health. Here there is but one opinion, and there are hopes long fostered that the time is not far distant when an enlightened Government will, with parental kindness, bestow upon us the advantages we claim. Reform, however, has so long echoed in our ears and occupied our thoughts, without the realization of any of these advantages, that many are nearly ready to despair about the results; and if any measure having some good in it be offered, it is seized with avidity, and accepted with humble expressions of gratitude. Our benefactors know this, and so do our enemies; and it requires the utmost vigilance and activity in the former to prevent the latter making us mere tools to gratify a fierce and dubious ambition. The seven-hilled city, which called herself eternal—whose temples and monuments bade defiance to the ravages of time, and whose armies triumphed over the world—fell by the wounds which her recreant sons inflicted on her under the cloak of friendship. In vain did the Roman Brutus strike even to the death his bosom friend, because he saw him flattering the multitude to trample on their liberty. In vain did Cato struggle for his country, and then pour out his blood—a libation to the gods—serenely hoping that he should yet behold another Rome, in a more congenial country, with better laws and beyond the reach of the tyrant's hand. The multitude had been beguiled, not at once, but by reiterated and covert attacks upon their liberty. Ill Rome existed only in name, and the stern citizen became an abject slave without energy or courage. As wise men, it becomes us to keep our eyes open, and our intelligence in activity. There is comparatively little danger to be apprehended, when that which is opposed to our welfare comes without any ornament to disguise its most unlovely features. Pseudo-reformers would of dare to offer to the profession any measure professedly for their welfare, without having something that is really good in it. Even the personification of evil is represented as being capable of making himself appear as a very angel of light, to accomplish his purposes. And men of fierce ambition can clothe themselves in the garments of good intentions, and adorn themselves with jewels purloined from the casket of benevolence.

The misnomer of the bill's title is surpassed by the viciousness of its contents. We have hitherto purposely abstained from bestowing any notice on the scheme, as we felt assured that the good sense of the profession would reject it directly it was published; and we have, moreover, no desire to come into more frequent collision with the author than the public welfare and our duty make necessary. We now say, however, in brief, after a careful examination of the measure, that, practically, a more insidious attempt to destroy the interests and degrade the status of the general practitioners of this empire was never before perpetrated.

It is not our intention to enter upon a minute dissection of the mass, but we cannot refrain from pointing out, that by the operation of the third and fourth clauses providing for a registration (*legally qualifying for practice*) of all individuals possessing only a single qualification, and by the twenty-third and twenty-fourth clauses, which would place in the hands of the Secretary of State an absolute control over the education of the members of our profession, with a distinct intimation that the qualification shall be different for the different grades of the profession, we de-

clare that by these clauses the utter destruction of the present high character of the general practitioners will ensue, and the profession will be placed in a worse position than it was before 1815.

The mode in which this bill has been quietly pushed through its first reading, and hastened on to its second, clearly proves that its author has no confidence in his own designs, and no expectation of their success. We have been accustomed to rebuke the state-craft of Sir James Graham: he gave us, at least, full time to consider every measure which he introduced into Parliament; but this Registration Bill was passed through its first reading without even the decent observance of the ordinary parliamentary form—that of giving an explanation of its provisions! The second reading was appointed to take place within a fortnight, and the bill itself was not published until the Wednesday previous to that on which it would be read. There was absolutely no time given to consider the measure. It was impossible that it could be passed through the hands of the profession, within the specified period. Public meetings could not be held to express an opinion of its contents. The darkest secrecy, the most indecent haste, were practised to pass a bill which his own experience should have foretold the author would disgust the profession and subvert, if successful, the interests of the general practitioners.

We have said that no time had been given to hold public meetings: we were in error. A large and highly respectable meeting of the profession, consisting of twelve members, was held on Monday night at the Freemasons' Tavern. We believe they resolved themselves into a committee to support the bill. It was, doubtless, a bold resolution, considering the weight of public reproach they will have to endure. We do not know how these gentlemen can look in each others' faces without laughing at the transparent humbug of their proceedings. Empey leaped into Mount Etna for the sake of fame, and there are some men who will do even worse than that—they will write themselves down asses rather than not be notorious. They may fire their crackers if they will, but they must take care that they do not burn their fingers.

While we thus write, in order to keep our professional brethren awake, we do not think for a moment that there is the least shadow of a chance of the coroner's Medical Registration Bill ever becoming the law of the land. It is the "old dodge" to fix immovably the tottering foundations of the Lincoln's-inn establishment. Now, if there be a post of honour in medical politics never to be yielded—if there be one sacred principle in our contest for professional amelioration never to be abandoned—it is that of undying hostility to the perfidious injustice of the new charter of the College of Surgeons. There can be no amity between the profession and that mismanaged institution while such a document remains to disgrace the collegiate archives; and we again repeat our unchanged resolution of never accepting that deed of injustice directly or indirectly as *un fait accompli*.

If we did not know that the bill, now nominally before Parliament in a triplicate or quadrupled metamorphosis, was but "an airy bubble," alike blown to excite and amuse public expectation—if we could fancy for a moment that there was any serious design of anything approaching to legislative action—we should advance against it in time this insuperable objection, that it involves

a legislative recognition and sanction of this monstrous wrong of the surgical portion of the profession. The bill, under present circumstances, is one for more firmly establishing the despotic powers of the College of Surgeons, and for more effectually degrading the general practitioners. Not a syllable is there in the whole document about the expediency of revising the College charter, or of giving a professional status to those who have been so long demanding this act of justice.

Mr. Wakley, as a medical politician certainly, has the powers of the chameleon, for he seems as if he could change his colour according to circumstances. We will endeavour to illustrate our meaning by reference to the bill or bills of Sir James Graham in 1844 and 1845, and the member for Finsbury's in 1847, and we will just note his consistency as a public advocate of professional improvement.

SIR JAMES GRAHAM'S BILL, WITH MR. WAKLEY'S COMMENTS, 1845.

EXORDIUM APPLICABLE TO BOTH.

By T. Wakley in 1844.

"As a preliminary to the examination of this summary, the members of the profession should recollect that they have been petitioning Parliament, during nearly twenty years, for a law which should confer upon them the right of governing their own medical institutions and affairs, through the instrumentality of a liberal and faithful system of representation. Now, then, for a recapitulation of the most striking and distinctive characteristics of the notable plan for placing medical practitioners, &c., under an improved system of administration."

Wakley on Bill of 1844.

"Is a system of registration a cure for the evils which afflict the profession? Can any system which directs the mere putting down the names of medical men in alphabetical order and in classes be attended with that relief from annoyance which has compelled them to present their petitions to the Legislature?"

"The arrangement which it contains must stand in a certain order:—1. Physicians; 2. Surgeons; 3. Licentiates in medicine and surgery.

"In a word, the plan for registering the members of the medical profession in THREE CLASSES is objectionable in principle, and must operate painfully and injuriously in practice."

Wakley's Bill of 1847.

1. "Names of Persons, &c., to be registered in a Book kept for the purpose.—Persons must register under one of the following classes:—1. Physicians; 2. Surgeons; 3. Apothecaries."

Wakley on Bill of 1844.

"The appointment of principal secretary down to the lowest clerk and messenger are all placed at the disposal of Sir James Graham. The appointment of messengers! What a noble occupation for a Secretary of State! But the duty is forced upon him; there is no choice; if he did not make the appointments the power of making them would be exercised by some of the members of the medical profession. Such an evil was not to be tolerated. What next? There is something curious, we opine, in the following clause. Sir James Graham having appointed all the principal and local secretaries, clerks, &c.,—they must determine what salaries such per-

See *Lancet* for 1844.

sons shall receive. We know well enough by whom the payments will be made, but the amount is the matter for consideration here; and, a friend or dependant being put in office, who so proper to determine the salary he shall receive as the party who placed him there? Accordingly, the Secretary of State appoints to offices, and then fixes the amount of salaries."

Wakley's Bill of 1847.

2. "Registrars to be appointed; the Secretary of State to appoint fit and proper persons for the office; also registrars, clerks, and officers, respectively, who shall have a salary, fixed by the Lord High Treasurer, and they shall be allowed reasonable travelling expenses by him, as he shall think fit."

Wakley on Bill of 1844.

"Any member of the council deputed to be present at examinations, and if regulations infringed, &c., to refuse register until the same be amended," &c.

"Here, then, is the grand contrivance of the Government for securing the efficiency of examination. What means, then, does the clause provide for securing such efficiency? 1. Returns may be required to be made; 2. A person deputed may be present; 3. Registration of testimonials may be refused."

Considering the object to be attained, the first two provisions are mere absurdities. The third carries with it the semblance of useful authority. But under what circumstances could the authority be exercised? And, moreover, we ask when would it be exercised? An examining body, anxious to possess the fees to be paid for diplomas, might strictly comply with the letter of the regulations of the council, and yet entirely evade them in spirit. In reality, the examination, as a test of acquirement and ability, might be wholly valueless, and the council not possess the slightest information which would enable it to interfere. When there are different examining bodies in different divisions of the same kingdom, "the best" securities for enforcing efficient examinations would be found in making the governing body of every medical college elective by the profession, rendering it imperative for examinations to be conducted in public, before the profession, &c.; and another would consist in paying the examiners by salary, and not rewarding them by fees proportionate to the number of candidates whom they might allow to pass muster.

Wakley's Bill of 1847.

"Inspection and Supervision of Examinations.—The Secretary of State may order returns to be made; may depute a person to be present at examinations; and if regulations infringed, &c., to admonish, and finally refuse to register till conduct of offending party be altered."

Wakley on Bill of 1845.

Persons not registered incapable of being appointed to Public Situations.—"All the directions contained in this clause, with the exception of the two last, are already provided for by the existing laws and the conventional arrangements of society. Persons who are not qualified by law are already excluded from offices in our public institutions. This section, therefore, offers no advantage to the profession or to the public."

"In all these provisions the profession may see why it is they are not allowed to choose their governing authorities, under the influence and sanction of a principle of medical representation. In every clause of the bill indisputable evidence is

furnished of the mistrust and dislike which were entertained by the framers of the measure towards the vast majority of the profession."

Wakley's Bill of 1847.

Persons not possessing certificates of registration incapable of acting as medical officers in public and other situations! &c. &c.

Wakley on Bill of 1845.

Privileges of persons registered.—Exempt, while practising, from all juries, inquests, corporate and parochial offices, &c.

"Privileges, indeed! What are they? Exemptions which all legally-qualified men at present enjoy."

"Privileges! Why, even these exemptions are not henceforth to be allowed if the practitioner be unregistered—in other words, if he have not paid (paid) for the insertion of his name in a certain printed list; so that this new privilege of exemption, as a substitute for the old, both being identical, is not to be had except at the price specified in the bill. Such 'privileges' should, undoubtedly, be known by another term, as they are the reverse of advantages. The 'privilege clause' ought to have been framed thus:—

"And be it enacted, that the exemptions which the members of the medical profession can now claim without cost shall not be allowed to them in future without being paid for."

Wakley's Bill of 1847.

Registered medical practitioners exempt from serving on juries, inquests, corporate and parochial offices, &c. &c.

Wakley on Bill of 1845.

Penalty for falsely pretending to be on the Register.—Guilty of a misdemeanour, &c., and punished by fine or imprisonment, or both as the court shall award.

"This clause is not worth a straw. It was thrown in as a sop at the end of the poisonous hash. It does not prevent any impostor from styling himself a physician or surgeon, or apothecary!"

Wakley's Bill of 1847.

Penalty for falsely pretending to be a Medical Practitioner.—To be fined not more than £10, nor less than 40s.

Shall we add one quotation more?

"Are not the qualified medical practitioners of the United Kingdom registered or enrolled in the institutions to which they respectively belong? Such undoubtedly is the fact. Thus the proposal of the Government amounts to this—that there shall be three registers instead of seven or eight. What an improvement!"

So much for the bill and the author's estimation of it. He has emphatically condemned it in advance. But then he can plead one circumstance in his exculpation. The bill he condemns is not his own, except inasmuch as he has bought it from the Queen's printer. He has borrowed every provision from Sir James Graham's offspring, omitting the good features, and deforming the indifferent. Pressed by his numerous engagements, he had no leisure to excogitate originality, or indicate an actual parentage, and he good-humouredly laid hands on the first little bill that came in his way. That one is unfortunately the very child which above all others he should have avoided. It has been too maltreated ever to be useful to him.

The advertisement of the National Institute gives the leading objections to this measure, and

these objections are so vital that no honest well-wisher of his profession can overlook them, or refrain from acting against a measure so pregnant with injury to the general body. We do not think that, at present, we need say more than to caution our readers against trusting in the artful and delusive advantages which are held out as likely to accrue from this measure if it could be framed into a law. There is nothing good in it which was not contained in former bills with more desirable concomitants; and all the evil is entirely its own. That evil is crushing and irremediable when once perpetrated. It is our business to prevent the evil being done. We advise our readers to petition strongly against it. The more briefly in space, the more quickly in time, the better.

MEDICAL POLITICIANS.

DR. LANCASTER, who had this week the high distinction of presiding over a public meeting of twelve (the modern apostles of a low civilization) had, it appears, one qualification for his new post of precedence—viz., a recent plucking at the College of Physicians. His associates, having no higher merit than that of being "pluck-able," of course yielded the *pas* to a gentleman actually "plucked." He had practically demonstrated the higher qualification in this *Lancasterian* school of low medical education, and became leader by that readily-acknowledged title of ascendancy. When resolutions are published in the newspapers under such a sanction, deference and respect are necessary results. Sir George Grey must readily accept a legislation so recommended!

THE HOUNSLOW CASE AND THE MEDICAL TIMES.

MR. WAKLEY having commenced proceedings in the Court of Exchequer, before Chief Justice Pollock, for substantially the same criticisms for which he had sought a criminal information in the Queen's Bench from Lord Denman, Mr. Lush, the eminent counsel, appeared for the *Medical Times*, on Saturday, before the court, and obtained a rule *nisi* to strike out the first count of the declaration served in the case. The plaintiff, by these attempted proceedings, also made himself liable to an attachment for contempt by the said court.

A BILL FOR THE REGISTRATION OF QUALIFIED MEDICAL PRACTITIONERS, AND FOR AMENDING THE LAW RELATING TO THE PRACTICE OF MEDICINE IN GREAT BRITAIN AND IRELAND.

The preamble sets forth the declaration, that the laws relating to the practice of medicine in the united kingdoms are numerous, complicated, and contradictory; and that the public possess no certain means of distinguishing between legally-qualified physicians, surgeons, and apothecaries, and mere pretenders to a knowledge of medicine; and that it is desirable that the names, qualifications, and places of residence of qualified practitioners should be duly registered by competent authority.

Clause 1. Provides for the Appointment of Registrars.—The Secretary of State, within one month after the passing of the act, to appoint three proper persons to be registrars—one for England, another for Ireland, and another for Scotland; also clerks and other officers for carrying into execution the provisions of the act; the Secretary to remove, at his discretion, any one of them, and to appoint others in their

places; their salaries to be fixed by the Lord High Treasurer, and reasonable travelling expenses allowed.

2. All moneys received by registrars to be paid by them into the Bank of England, as the Secretary of State shall direct, to the credit of the Lord High Treasurer, in the name of the "Medical Registration Fund of Great Britain and Ireland."

3. Registration of Names, &c., of Persons qualified to practise before the passing of the Act.—The name and place of residence, legal qualification or qualifications, with date, of every physician, surgeon, or apothecary, who shall produce a diploma, &c., or proof of having one, to be registered without fee; also those who were actually practising prior to 1815, and who shall sign a declaration according to the form in schedule (A); also every surgeon and assistant-surgeon of the army and navy, and in the East India Company's service.

4. Registration of Persons obtaining their Qualifications after the passing of the Act.—Such persons, on the payment of two pounds, to have their names, places of residence, and qualifications registered.

5. Registrars to issue annual certificates to registered practitioners on application, and according to the form in schedule (B). Registrars to issue certificates only for those parts for which they are appointed.

6. Payment of five shillings for certificate, to bear date on the day on which it shall be issued, and continue in force till 31st of December. Registrars on 15th of December to issue to persons registered, and making application, on payment of five shillings, a fresh certificate.

7. Registrars to keep a Record of Certificates.—A record to be kept of every certificate issued, and in the month of January a register to be printed according to the form in schedule (C); the register to be called respectively "The Medical Register for England," &c. A copy of this to be evidence in all courts, &c.; and the absence of any person's name from it, until the contrary be made to appear, shall be evidence that such person has not obtained a certificate. Registrars to be furnished on application, upon the payment of one shilling.

8. Persons accidentally omitted from Register may obtain Certificate on paying twenty shillings.—A person entitled to register, and who shall prove to the satisfaction of the registrar that through his own neglect or mistake his name has been omitted, or that he intends commencing or resuming practice, or changing his residence before the 1st of January in the ensuing year, to have a certificate on the payment of twenty shillings.

9. Repeal of Restrictions on Practice, excepting such as are in this Act.—Acts or charters granted before the passing of this act, prohibiting persons from practising medicine, &c., without such license as is mentioned in the act or charter, to be repealed.

10. Registered Persons entitled to Practise when Certificates are issued.—A person registered, and possessing a certificate according to the provisions of the act, entitled to practise without other license.

11. Registered Practitioners entitled to charge for Advice, Visits, and Attendance.—To be recovered in any court of law with full costs of suit.

12. None but Registered Persons to recover Charges.—A certificate in force, or proof of legally practising in the capacity in which the practitioner claims such charge at the time when the debt was incurred, necessary to its recovery.

13. Repeal of enactment requiring five years' apprenticeship to an apothecary.

14. Summary Penalty against Unregistered Practitioners.—Any person not being on the register, and not having a certificate, who shall practise as a physician, &c., shall, on conviction, forfeit not more than five pounds, nor less than forty shillings, or be recoverable within three months.

15. Penalty on Unregistered Persons for acting as Medical Officers. Any person accepting an office, medical or surgical, for which he is not qualified according to the act, and practise in such office,

to forfeit not more than ten pounds, nor less than forty shillings.

16. Expulsion of Registered Practitioners for Disgraceful Conduct.—If any registered person shall complain to the council of any college or other governing body, that a person having their diploma has conducted himself in a disgraceful manner, the council empowered to cite the accused person before them, giving him due notice and a full statement of the charges against him. If the charges are proved, the name of the person to be erased from the roll of the college and from the register for ever; unless the governing body by whom the name was first erased shall readmit him.

17. Persons not possessing Certificates incapable of acting as Medical Officers in public and other Situations.—from a hospital down to a friendly society for affording mutual relief in sickness or old age. Their certificates not to be received in a court of law.

18. Penalty for wilful falsification of the Record of Certificates by any Registrar.—A person so offending to be imprisoned for a term not exceeding six months.

19. Penalty for obtaining Certificate by false Representations.—To be deemed guilty of a misdemeanor; and, on conviction, to be imprisoned, with or without hard labour, for not more than six months.

20. Penalty for falsely pretending to be a Medical Practitioner.—An unregistered person assuming to be so, on conviction before a magistrate, to pay not more than ten pounds, nor less than forty shillings.

21. How Penalties are to be recovered: if not paid, the Offender may be committed.—A magistrate may hear and determine a complaint on the oath of one or more witnesses; and, upon the non-payment of the fine, may commit the offender to gaol for one month when the sum does not exceed forty shillings, and for three months when it does not exceed ten pounds.

22. Application of Penalties.—To the Medical Registration Fund.

23. Uniformity of Education, Qualification, and Fees, throughout the Kingdom.—The several colleges shall lay before the Secretary of State a scheme of education, including midwifery, of the course of study, and particulars of the examination to be passed by all persons applying for letters-testimonial as a physician, &c., with an account of the fees proposed to be taken. The qualifications and fees to be uniform, according to the nature thereof, and these of no force unless sanctioned by her Majesty.

24. Inspection and Supervision of Examinations.—The Secretary of State may require returns to be made respecting the examinations, &c., and may depute a person to be present at them, and to make a report. If the regulations approved by her Majesty be infringed, the examining body so doing to be admonished; and if the admonition be neglected, the registrars to refuse to register upon the testimonials until the Secretary of State be satisfied.

25. Examiners may take candidates to hospitals, workhouses, &c., for practical examinations.

26. Act not to affect Students of two years' standing.—Such persons being allowed to complete their education, and pass their examinations, as if this act had not been passed.

27. Act not to extend to dentists or coppers in business before 1st of March, 1847.

28. Act not to affect the business of chemists and druggists.

29. Registered medical practitioners exempt from serving on juries and inquests.

30. Names of Criminal Practitioners to be erased from the Register.—Any one guilty of a crime inferring infamy, or the punishment of death or transportation—of obtaining a false certificate, giving a false statement, evidence, or certificate—upon conviction shall have his name erased, and lose all the privileges of a registered medical practitioner.

31. Interpretation Clause.—The words "physic" and "medical" mean in this act "physic," "surgery," and "surgical."

32. Act may be amended.

HOUSE OF COMMONS.

Wednesday, May 5.

Mr. Wakley moved the order of the day for the second reading of the Medical Registration and Medical Law Amendment Bill; but after some conversation between Sir G. Grey, Mr. Hume, Sir J. Graham, and Mr. Wakley, the second reading of the bill was postponed till Tuesday next.

[To the Editor of the Medical Times.]

SIR,—Permit me to make a few observations upon the new Registration Bill, now before the public. I claim this more on account of the circumstances in which I have been placed, than from any superiority of discernment above that of my professional brethren. I have for the last few years watched with considerable interest the different bills and plans which have been proposed as a substitute for that justice which the general practitioners of this country claim at the hands of our Government, and which cannot be denied them if they will only unite. But I can state with great confidence, that there has been no bill, either proposed or introduced into Parliament of late years on the subject of medical reform, that has had embodied in it so much that is directly and decidedly injurious to the future welfare of the general practitioner as the Medical Registration Bill now before us. It is very painful to think that a bill so manifestly unjust should be allowed even to be introduced to the notice of Parliament, and I am sure it makes a larger and a louder claim for a comprehensive and equitable scheme of medical legislation than could be uttered by the general practitioners themselves. The bill is in every respect put together for the purpose of crushing them. Its very title is intended to deceive as many as it is possible, and especially those who are not aware of its design. Taking for its preamble, the plea that there are numerous complicated and contradictory laws relating to the practice of medicine, it seemed desirable that the names, qualifications, and residences of all legal practitioners should be registered. This is the substance of the preamble, and all, therefore, that the act ought to contain. Accordingly, after this we are prepared for an act which is simply to make registration imperative on all those who wish to practise legally—the clauses being strictly confined to the carrying out of this object. But what must be the reader's surprise when he finds at least half-a-dozen other subjects, all far exceeding in importance and interest even the subject-matter of the preamble? Surely they cannot be introduced in this way unintentionally, on account of the little weight that is to be attached to them: for, independently of this being an unreasonable supposition, all who are in the smallest degree acquainted with medical polity must be assured that many clauses not alluded to in the preamble contain individually sufficient subject-matter for a separate act of Parliament.

The bill before us, then, is not merely *de medicis et chirurgis registratione*, but, we may be permitted to add, *de omnibus rebus et quibusvis aliis*. On this ground alone I have not a doubt in my own mind that the bill will be thrown out; nevertheless, it may not be altogether unprofitable to bring before the reader's notice a few of the clauses which have been so craftily introduced, not only on the subject of registration, but also on apprenticeship; on the conduct of members of the different colleges; on the education, qualification, fees, inspection, examinations by supervision of the Government; and lastly, upon the effect this bill is to have upon druggists, as set forth in the 28th clause, the great master clause of the bill, which has been constructed such a manner as to allow the only class of people to go loose who alone really required to be tied up by the bill in question. First, then, on the subject of registration in the third clause, which gives directions as to qualified persons: the registrar is empowered to receive any diploma, certificate, or license, granted by any English, Scotch, or Irish university, or any cor-

poration, society, or college, and to give in return the registration certificate (clause 5), which certificate by a subsequent clause (10) is made sufficient to practise legally without any other license, but only in that part of the United Kingdom for which the certificate was issued. Now, let us see the extreme and unnecessary inconvenience which this clause would entail upon Scotch and Irish graduates, whose capabilities of practising, without danger to the public, could no more be disputed than those who are members of English colleges. If this is purely a Registration Bill, the capability to practise having been decided, we contend that its great object ought to be rather to check the unlawful practising of druggists and quacks, than to look with jealousy upon those who have as a body quite as much claim on the confidence of the public as the English general practitioners, and far more than the pure surgeons, whose deficiency in the knowledge of medicines and their action upon the human body has now passed into a proverb. Yet the bill in question hesitates not to give the certificated license to practise medicine, midwifery, and what not, to the man who can bring a diploma from the College of Surgeons of England—a college which is disgracing the profession by giving its members their diploma almost without examination. Why, the College of Surgeons could not, if it wished, grant a license to practise medicine; how then can its diploma alone, which barely sets forth its members as capable of undertaking the "ordinary exigencies" of surgery, in any decency pretend to have its members registered as legally-qualified to practise medicine? As well might a member of the Geological Society make a similar claim, and not without reason: for the College of Surgeons, as a body, think much more of the bones of some extinct creature, though their thinking is to so little purpose on that subject even, than they do of the art they profess to teach. This part of the bill that bears upon the subject of registration—that actually condescends to confine itself to the subject of the preamble—is so obviously unjust towards the Apothecaries' Society, that, if it were allowed to pass, this valuable society, which has done more to maintain the status of the general practitioner than any other college or society in the kingdom, would pass into complete desuetude—the immaculate, disinterested College of Surgeons taking its place. *Quantum in rebus inane*. We trust, if we are to have legislation, it will not be such as to throw us back, but such as will carry us forward.

By the 13th clause of this bill, one of the most important clauses in the Apothecaries' Act of 1815 (56 Geo. III., c. 191, s. 15) is proposed to be repealed, without the slightest allusion to any plan which is to supersede it. So that the progress of civilization, and the advance which society necessarily makes in the course of thirty years, and particularly in education, having rendered a clause in the old act comparatively ineffectual, though it still exercises much useful restraint, this bill proposes to repeal it, and that not for a better one, forsooth, but for none at all. Probably all are ready to admit that the old apprentice clause might have been advantageously amended long ago; but to contemplate its repeal without offering any sort of substitute argues a carelessness and a want of thought for the welfare of the rising members of our profession during a period when they are most in want of some one to advise and direct them aright. If this bill were in all other respects faultless, and this clause were allowed to remain, it ought never to become an act of Parliament.

The 14th clause proposes to transfer the power of prosecuting for illegal practice out of the hands of the Apothecaries' Company into those of nobody—making the registrar's certificate the protection, and the absence of this certificate the plea for conviction. Thus, by these five clauses, the 3rd, 9th, 10th, 13th, and 14th, the Apothecaries' Society are deprived of every power of control they now possess over illegal practice, as well as over the education of their candidates.

The 23rd, 24th, and 25th clauses are most important for consideration, seeing that they aim directly at a great principle in medical polity, that has more depending on its issue than any other single question now agitating the minds of medical men generally. If a comparison is made between the mere question of registration and this of the interference of Government in directing the examinations and other matters relative to the candidates and members of the medical profession, we may fairly put it down in figures as one stands in relation to a thousand. If the profession of medicine is ever made to take its proper stand in the society and institutes of this great country, it will be subsequent to, and not before, that period when the colleges retained the power of granting degrees and licenses to practise medicine and surgery. What would be said if such a college as Brasenose or Queen's had the power vested in it of granting degrees in divinity, or giving licenses to hold the rank of a deacon or a bishop, as the case might be. But the question is far too important to be tacked on to a mere bill for registering names; and a conscientious Minister like Sir G. Grey would never give his consent to such a principle, however much he must approve of it, being introduced in so ungarded and inconsiderate a manner as an attempt has been made to do in the bill before us. As I have some foundation for believing Sir George Grey to be high in principle, and really desirous for the welfare of all branches of the profession, I shall rest in the thought that he will never allow the interference of Government in our colleges to be made the law of this country until he has placed every branch of the professions, not only of physicians and surgeons, but also general practitioners, in an equitable position one towards the other.

I have finally to make a short remark on the 28th clause of the bill, which I do not know how to hold up to my professional brothers in too wicked a light: whether to regard it as most dangerous for the circumstance of its having been introduced in order to sweep away the very little amount of good which a correct registration only would afford, or for the extreme folly it casts upon the whole bill, by permitting all those unlawful practices pursued by druggists to continue unchecked, which ought to have been the primary, if not the only, reason for its introduction. But I have said enough to put the profession on their guard, and here I will conclude. —I am, Sir, your faithful servant,

Alton, May 5.

C. M. BURNETT.

COURT OF QUEEN'S BENCH—MAY 4.
(Before Mr. Justice Coleridge.)THE QUEEN v. THOS. WAKLEY, ESQ., M.P., AND
CORONER.

Mr. Warren, with whom was Dr. Lane, applied for a rule calling upon Thomas Wakley, M.P., and coroner for the western division of Middlesex, to show cause why a criminal information should not be filed against him at the instance of Dr. Warren.

Mr. Warren said: My lord, I am here on behalf of Dr. Warren, who in June last was surgeon to the 7th Hussars. The affidavit states that Dr. Warren has been for thirty years in her Majesty's service, and is a Doctor of Medicine. On the 15th of June, private White having been tried, for drunkenness and for striking a superior officer, by a court-martial, was to be flogged, the sentence having been previously communicated to head-quarters, and confirmed. Dr. Warren took care to make himself acquainted with the condition of White, and ascertained that he was able to undergo the punishment. On the morning of the 16th of June he examined him carefully, and found that he was in perfect health and capable of undergoing his punishment. He also asked the poor man if he had any complaint by which he was not fit to receive the punishment, and, as there was none, it was his painful duty to certify to that effect. It was also his duty to witness the infliction of the punishment, which

he did, in the presence of Captain Shirley and several other officers. He stood close to the sufferer and most carefully and anxiously watched him, in order to ascertain if he grew unfit for the infliction of more punishment. He saw nothing like faintness or anything to indicate that he was unable to bear the infliction, nor was any complaint made. It was inflicted without any undue severity whatever; and in the absence of any complaints of physical incapability he (Dr. Warren) had, according to the regulations of the service, no power whatever to interfere. After receiving his punishment, White walked into the hospital without exhibiting any undue effects of its infliction; Dr. Warren attended him and fomented his back, and perceived nothing calling for particular notice. He gave him such directions as were necessary, but no marks of extreme suffering were visible on the back, and he went on well. Ten days after this, Dr. Warren perceived a few boils of an ordinary character forming on White's back, which yielded to poultices. Dr. Warren continued to attend him regularly to the morning of the 6th of July. On the 4th of July he found him in a proper position for being removed. On the evening of that day he called upon him and found his pulse accelerated, and other symptoms showing inflammation of the pleura to be taking place; he gave him the best advice he could, and continued to attend him. On the morrow he found, to his great astonishment, that this man had, voluntarily and of his own free will, offered to scrape and clean out the ward, and, besides this, to do the same thing in the dead-ward. The affidavit states that on that day the heat was more intense than it had been known for forty years, the thermometer standing at 88°, and the said dead house or ward was cold and exposed to constant draughts and currents of cold air, and that his presence there was highly dangerous to one liable to disease of the lungs, heart, or pleura, and especially as White would be, from the labour in which he was engaged, in an excited state and perspiring, and that this was sufficient to account for the accelerated pulse, and would hasten on the incipient inflammation. On the morning of the 6th of July he found him complaining of acute pain in the region of the heart, which Dr. Warren noted and prescribed for accordingly. He continued to attend him to the 11th of July, and at half-past eight he died.

It was contrary to the regulations that a person who was not suffering of a surgical injury should remain in the surgical ward, and on the 10th he was removed to the medical ward. Finding that the case was likely to end seriously, he communicated with Sir James McGrigor, who sent down a military medical officer, a first-class staff-surgeon, Dr. John Hall, who has since been made an inspector of hospitals. Dr. Hall went at once to White, and attended him to his death, and concurred with Dr. Warren in his views of the treatment which had been adopted. When death had taken place, according to the requirements of the army regulations, a *post-mortem* examination was made by Dr. Reid, in the presence of Drs. Warren and Hall. On this part of the case Sir James McGrigor, who is at the head of the medical department of the army, makes oath, and says—that these officers were men of the highest honour and integrity, and able to make a proper and competent examination of the body as to the cause of death. The body was opened by Dr. Reid, and examined with the greatest possible care. In all these matters the regulations of the army have been rigidly adhered to; when the examination was concluded, he made a report, in which it is said—"there were marks of corporal punishment across the shoulders, particularly over the right scapula; but the punishment does not appear to have been severe, and the part where it was inflicted was quite healed; the back was discoloured from the granulation of blood since his death." A portion of the integument dissected off the shoulder and the parts below was given to Henry Potter, who was directed to place it in spirits of wine, the usual mode

of preservation. In the ordinary manner a certificate was sent in on the 13th of July, which goes on to state that the deceased died of inflammation of the pleura and of the lining membrane of the heart, and that the cause of death was in no wise connected with the corporal punishment which deceased had undergone. Thus it rested till application was made to bury the body, by which time it appeared that rumours had gone abroad that something cruel had been connected with the cause of death. When the man who was sent to Heaton to make arrangements for the burial was asked of what complaint the man had died, he replied "of liver complaint." Dr. Warren makes affidavit that he never authorized the man to say thus, and he does not know how or why he made such answer. On this Mr. Triumner, the clergyman, informed the troop sergeant that he had heard that rumours were afloat about the man's death, and that he would not bury him without a coroner's warrant. Mr. Wakley sent his messenger to the barracks to make inquiry concerning the circumstances of death, to whom the officers and others connected with the barracks gave every information and facility, with full permission to see the body. Colonel Whyte also gave orders for the attendance upon the messenger of all who from their knowledge of the case could throw any light upon it. In Mr. Wakley's letter of instructions to his messenger it is said, "It should be stated whether any surgeons have opened and examined the body." The messenger was informed at the barracks of all that had taken place. Mr. Wakley is, therefore, fixed with a full knowledge of the facts of the case as it stood at that time, and he should have felt that the responsibility of his office required of him the greatest calmness and fidelity. The affidavit states that neither Dr. Warren nor, to his knowledge, any one connected with the regiment mystified the subject, or threw any obstacle in the way of a right understanding of the facts by the coroner.

On the 14th of July the warrant summoning the jury was issued, and, through the adjutant, the officers and medical men of the regiment were ordered to attend on the 15th and give information. Dr. Warren, Lieutenant Ireland, Captain Shirley, and several others were there on the morning of the 15th to assist the coroner by their evidence and information, and in every way in ascertaining the facts of the case. Reports were prevalent in the neighbourhood, which, however, did not attribute the death of White to any bad conduct of the deponent until after the coroner wickedly and maliciously, by wilful and unlawful acts, had pointed out Dr. Warren as the man on whom the charge should rest. The first thing he did was to ask every witness if he had supplied to the barracks any articles in sale, and on these grounds he rejected not less than six witnesses who would have given evidence before the jury. Dr. Warren accompanied the coroner and jury to the barracks, and rendered all the assistance which was in his power, and when one of the privates was asked by the coroner to turn over the body for the purpose of inspection, and was unwilling, it being in a state of decomposition, with his own hands Dr. Warren assisted to turn over the body for the coroner and jury to see. The skin had on a former occasion been delivered to Henry Potter, and Dr. Warren did not, when unexpectedly applied to for it, know where it was to be found, but he immediately sent for Henry Potter, who attended and produced the said skin to the jury; yet, notwithstanding this, the coroner unlawfully, wickedly, and maliciously, and in order to prejudice the minds of the jury, insinuated in their hearing that the absence of the skin was a most suspicious circumstance. Captain Shirley presented himself before the coroner to be examined, and his evidence was taken and heard by Mr. Mills, the deputy coroner, in the absence of the coroner and jury, and while the latter were gone to the barracks to see the body, with a view to such statements being sworn to on their return.

Mr. Justice Coleridge: Is that the practice in the Coroner's Court?

Mr. Warren: No, my lord; and that is a most important point in the inquiry. Captain Shirley was told to continue in attendance, and to hold himself in readiness to be sworn, and to answer any questions that might be put to him. On the return of the coroner he cast his eye over the deposition of Captain Shirley, and asked other questions on them. He never, however, swore Captain Shirley, nor submitted his evidence to the jury, though it was most important. This, my lord, is very material. At the several adjournments of the court Dr. Warren and the other medical and military officers were in attendance, ready and desirous of being sworn and of giving evidence; but Dr. Warren was not sworn and examined upon oath at all at the inquest.

Mr. Justice Coleridge: Might there not be a reason for this?

Mr. Warren: Perhaps, so, my lord; but he did not bring the evidence fairly before the jury: he omitted and purposely excluded some from their knowledge. With respect to the piece of skin also, of the absence of which he had received a fair and reasonable explanation, he persisted in stating that a portion had been concealed or destroyed, and said that not one-fifth part of it had been produced, and that it would not correspond with the back; and that such a fact looked very suspicious. When it was attempted to be stated that the skin had drunk in the spirits of wine, and that if properly stretched it would fit the back, the coroner interposed and unlawfully prevented such explanation from being received; his observations thus went to the jury, who were prevented receiving the reasonable explanation of them. Dr. Warren next complains that, although the coroner knew that he had attended the deceased for some time previously and up to his death, and had made a *post-mortem* examination, he yet refused to examine him, which was contrary to the provisions of the statute; but appointed one Mr. Horatio Grosvenor Day. The statute to which I refer your lordship is the 6th and 7th William IV., chap. 89, sec. 2, and provides that if the cause of death is not made clear by the testimony of the medical men who had attended the deceased, the jury may name another: showing that previously they should hear such evidence as they have. This course of conduct Mr. Wakley must have taken knowingly. Then a Mr. Christopher Teuten, a reporter, attended the inquest and took shorthand notes, the coroner knowing, as Dr. Warren believes, that such notes would be published, and stating to the jury that publicity would be given to the proceedings: thus showing the *animus* of his proceedings.

Mr. Justice Coleridge: What *animus* do you impute, Mr. Warren?

Mr. Warren: A wish and intention, my lord, to prejudice the minds of the jury and the public. The affidavit goes on to say that the coroner, on his return to London, invited the reporter to ride with him in his carriage, and then and there asked him to suppress a portion of his report, viz., the full evidence of Captain Shirley and Private Rising, and he, the coroner, suppressed that evidence subsequently to the jury. Dr. Warren complains that these publications have created grave suspicions, and raised against him great prejudice as well as against the other officers, as to the cause of the death of White. Drs. Hall and Reid also attended the inquiry, but were ordered by the coroner to be excluded; by which means many partial statements were allowed to remain and go to the jury, without such correction and explanation as they might have been able to supply had they been present, and that such partial statements were published without such explanation. The officers of the regiment were also by the same authority excluded, and many private soldiers who had been tried and convicted by courts martial were examined, from whom the coroner elicited certain things in nowise relating to the cause of death. Dr. Warren then goes on to say that neither he nor the officers of the

regiment had any knowledge of Mr. H. G. Day, and that he exhumed the body and examined it as to the cause of death, and came to the conclusion that there was no connection between the punishment and the death which followed. But Mr. Wakley refused to allow even his own nominee to give evidence to the jury, when this was its substance, and he prevented him from being examined. He ordered him to retire, and in his absence induced the jury to believe that he had made an improper or incomplete examination, and said that another person must be nominated to make examination. With the desire of obtaining evidence to criminate Dr. Warren, he called in Mr. Erasmus Wilson, a private friend, who was or had been connected with him, and who was under some kind of obligation to him, and had been sub-editor of the coroner's paper, the *Lancet*. He afterwards gave him orders to examine the body, excluding every one from such examination, except Mr. Day. This was in very hot weather, and when the body was in an advanced state of decomposition. Then, my lord, we have three affidavits, in addition to Dr. Warren's, swearing that in a midday adjournment Mr. Wakley had a private interview with two of the witnesses, Matthewson and Ellsworth, who had been before examined, and whom he subsequently again examined. The coroner called to give evidence this person named Ellsworth, who had been twice tried for desertion, and seven times for other offences, from whom he took some false statements calculated to prejudice the minds of the jury and to mislead the public with regard to the flogging. Of this person the coroner asked if Matthewson had not been punished for giving evidence, but that the witness was compelled to admit it was on no such account. The coroner also said that he should call neither Dr. Warren nor Colonel Whyte, but that, if they wished to state anything, he would take down whatever they might say. But, when they offered to give evidence, the coroner wilfully, maliciously, and wickedly, to make it appear that they stood in the position of persons who might become chargeable with the murder of White, told them that he should have to charge the jury as to the cause of death, and that he could not swear Dr. Warren, and further warned and cautioned him that he was about to make a voluntary statement, and unlawfully took the evidence of Dr. Warren without his being sworn to any part, although Dr. Warren persisted in requiring to be sworn. Drs. Hall and Reid and Mr. Day concurred in the opinion of Dr. Warren, that the death was not at all in consequence of the flogging, but of inflammation of the pleura and of the lining membrane of the heart. After this Mr. Wilson was called, and here the affidavit of Mr. Day states that, when with him Mr. Wilson saw and examined the body, he agreed in opinion with him (Mr. Day) and with Drs. Hall and Reid as to the cause of death, but that when he was called by the coroner to give evidence to the jury, he then stated that he had observed certain morbid appearances quite new to him and to the science of physiology, and which were not described in any books. On the fourth and last sitting of the jury, on the 3rd of August, the coroner produced a letter, and, without inquiring into the truth of the statements it contained, he proceeded to read the letter to the jury, and examine witnesses as to the truth of its statements, when it came out that these statements were flagrant falsehoods. By these representations great excitement had been raised throughout the kingdom, and reports were circulated that the deceased had been murdered, and that for allowing the same Dr. Warren was liable to be indicted, and that Drs. Warren and Reid had removed and concealed a portion of the skin. By these statements, and by the conduct of the coroner, the private soldiers of the regiment were encouraged, to gain favour with the coroner, to contradict many statements of other witnesses, and proceeded to many acts of insubordination. The affidavit then states that the coroner offered a sum of money towards procuring

the discharge of two of the men named Matthewson and Cook. When, further, Dr. Hall proceeded to explain that the opinion of Mr. Wilson was not to be relied on, the coroner obstructed and prevented him, and would not allow such explanation to be given. The coroner then addressed the jury as follows:—"I trust the past will be a lesson to those who have been desirous to avoid this investigation." My lord, the medical and military officers were in constant attendance; they had, moreover, provided both mounted and foot orderlies to go off at a moment's notice. "In this case," he says, "there has been a deliberate attempt to keep back the truth." Thus, my lord, throughout does he steadily endeavour to prejudice the minds of the jury against the medical and other officers. On the 19th of August, Mr. Wakley was at a meeting at Exeter Hall, and made strong criminatory observations on the part which the officers had taken. In September following, advertisements were inserted in the *Lancet*, of which Mr. Wakley is proprietor, asking for subscriptions for obtaining a testimonial to himself as coroner. He also applied for an information against the *Medical Times*, and your lordship knows what judgment was then pronounced. Pending the decision of this court in that case, Dr. Warren abstained from making any application of this kind; but since that decision his attention has been called to some unlawful acts performed by the coroner during the time, showing that at that time he was unlawfully endeavouring to prejudice the jury against him. The transaction to which I now call your lordship's attention is one which to my mind presents itself as an instance of most remarkable and extraordinary conduct in a minister of justice. The affidavit states that the coroner did wickedly give instructions to a certain counsel—the name I do not state, there are particular reasons why I should not, but it can be mentioned if your lordship wishes it; and were I to mention it, your lordship would recognise it as among the most eminent, perhaps the most eminent, of special pleaders—to draw up and prepare a verdict charging this deponent, Dr. Warren, with the death of private White, and that this took place before he had charged the jury. These instructions were returned by the eminent counsel referred to, who refused to take part in such matter. It is impossible, my lord, to conceive of conduct more —

Mr. Justice Coleridge: Does the deponent affirm this upon oath of his own knowledge, or does he state that he is informed?

Mr. Warren: He is informed, and verily believes it, my lord.

Mr. Justice Coleridge: Ought a grand jury to find a bill when a person merely says—"I believe such and such things"?

Mr. Warren: This, my lord, is quite a different case; he here was present as a judge, to do judicial acts. I have the name of the party to submit to the court, and if they dispute the fact, that will appear in their answer.

Mr. Justice Coleridge: But if the counsel, making the same objection as I have been doing to the sufficiency of the evidence, makes no answer to it?

Mr. Warren: Surely, my lord, I submit he must deny it. On the 11th of March a public meeting was held at the Craven's Head, in Drury-lane, and I have here the placard by which the meeting was convened. It was a public meeting, according to the bill, to take measures for completing the subscriptions necessary to the discharge of Matthewson and Cook from service in the army. This was after your lordship had discharged his motion. The bill says that the meeting will be attended by "Thomas Wakley, Esq., coroner for Middlesex, and at the Hounslow inquest," and that he and others would address the meeting.

Mr. Justice Coleridge: But how do you seek to fix him with that placard, Mr. Warren? Might not that have been issued and he not have been a party to it?

Mr. Warren: My lord, it was issued long before the meeting was held, and he cannot be

supposed ignorant of it. He attended the meeting as coroner.

Mr. Justice Coleridge: As coroner, Mr. Warren?

Mr. Warren: As coroner, my lord; not in the sense that he went to discharge there the functions of that office, but it was the fact that he was the coroner and had been concerned in the inquest that gave an importance to his attendance. When there he made the following remarks—"Mr. Chairman, I do not see"—

Mr. Justice Coleridge: With the publication of these remarks?

Mr. Warren: No, my lord, but with having addressed them to a public meeting.

Mr. Justice Coleridge: How do you do that?

Mr. Warren: By the affidavit, my lord, of the shorthand reporter, who was present.

Mr. Justice Coleridge: What are the words of the affidavit?

Mr. Warren: That the deponent was present at the meeting and took shorthand notes, of which this is a copy; and that he has compared this report with his notes, and he says that it is a true and correct report. He states, my lord, in this speech, that he is satisfied that, in the prosecution of his great object, he had the sympathies of the public, and that the privates were, and are, exposed to persecution on account of the evidence which they had given. He then says that these men appeared to give honest testimony; thereby impugning, indirectly, the testimony of some of the other witnesses. Imagine the effect of this upon Dr. Warren. He then, my lord, has the presumption to say that his conduct has led Lord Denman to deny him justice, to which I particularly call your lordship's attention. He then says: "A calumnious public writer had charged me with having participated in the fees of the inquest with one of the medical witnesses, and I moved for a criminal information. Shortly after the publication of this calumnious statement, I was attacked in the House of Commons, and I defended myself. But what does the Court of Queen's Bench do? It alleges as the chief reason for denying me its protection that I had taken the law into my own hands by this defence which I made in the House of Commons, so that, because I would not hear a foul libel against me repeated without a word in reply, I am denied justice in the highest court in the kingdom. Well, the Chief Justice complains that I did not call the medical witness who had attended White. Now, White had been flogged twenty-six days before his death, and had been taken into the surgical ward of the hospital, and very properly, because it was a surgical case—they had made it so by inflicting a wound; he was taken into the ward, and kept there for twenty-five days; but when his legs and bladder were paralyzed, he was taken in that helpless state, against his own wishes, into the medical ward, to make it appear that he had died, not from a wound, but from internal disease. No attempt was made to deny this at the inquest, and I could not call that witness safely who had attended the deceased under these circumstances. What did Lord Denman say? He said that that medical officer was placed in a most perilous position. Lord Denman stated that, if that witness had stood by and seen too much punishment inflicted on White so as to cause his death, he would have been responsible for such loss of life; and yet that is the witness whom I should have first put into the box! A man who may be liable to a charge of murder is to be put into the witness-box, to give his testimony to the jury!"

Mr. Justice Coleridge: Supposing, Mr. Warren, that you had been coroner, what would you have done?

Mr. Warren: Why, my lord, if it were a person of education and known honour and integrity, I would examine him.

Mr. Justice Coleridge: That would be, no doubt, in the exercise of your judgment; might not a person honestly come to a different judgment?

Mr. Warren: My case is, my lord, that all this was done with explicit design and intention, and

dishonestly. He then, my lord, has the boldness or audacity to say, "I am satisfied that no one could have more misstated the law than Lord Denman has done in this case, and it remains the duty of an inferior coroner to correct the mistakes of the chief coroner of this kingdom." These, my lord, are acts done and statements made by an officer of a court of justice.

Mr. Justice Coleridge: Now, Mr. Warren, you apply for a criminal information on the ground of improper conduct in discharge of the duty of coroner, and are acting as the Attorney-General, which I think is not within your competence.

Mr. Warren: Dr. Warren, my lord, is, I submit, entitled to charge him with this, and thus establish a case for the intervention of this court. I think the case of the *King v. Watson*, contained in the "Second Term Reports," p. 199, bears me out in this view. Mr. Wakley, notwithstanding the decision of this court against him, and his own refusal to admit important evidence, now seeks to destroy by representations of this kind the peace of mind of Dr. Warren. Your lordship has also to say whether by these remarks the administration of justice is not in danger of being brought into contempt. Judge Buller says, "Nothing is more important than to put a stop to wanton attacks upon the manner in which justice is administered, since for every wrong there is a remedy; but that any person who, by publication or any other means, seeks to calumniate the proceedings of a court of justice, by such conduct tends, by weakening the estimation of justice to sap its very foundations." Not satisfied with declaring that he was denied justice, he says that Lord Denman had misstated the law, and that it remained the duty of an inferior coroner to correct the mistakes of the chief coroner of this kingdom. Dr. Warren has done everything in his power to stand well with his fellow-men; but, after his character has been vindicated in a court of justice, the coroner impugns the justice of that decision, because it had censured his conduct and protected Dr. Warren, and says that justice had been denied. But if so, then Mr. Wakley was right, and Dr. Warren wrong. I put it to your lordship, that Mr. Wakley had no *bond fide* belief that Dr. Warren would be found criminal, but that from first to last he was actuated by a determination to seize upon everything which would help to get up a case against him and the other officers. Accordingly, the jury returned a verdict quite conformable, if not to the evidence, at least to the charge—that deceased died from the effects of a severe and cruel flogging. Thus, in spite of the unimpeachable statements of the medical officers, and in spite of the testimony of their own nominee, Mr. Day, they return a verdict bearing out the summing up. These are, my lord, the circumstances of the case: they have not been brought forward earlier because Mr. Wakley was already, on his own application, before the court. Upon the discharge of that application, Dr. Warren found that those instructions which I have referred to had been sent during the progress of the inquest. It was far from his feeling to wish again to enter into the matter, but Mr. Wakley has taken another opportunity to wound him as in the apple of the eye, and makes use of your lordship's court for this purpose. There is evidence of a complete, systematic course of conduct on the part of Mr. Wakley, with a view to injure Dr. Warren in his character, in personal estimation among his friends, and in every way in which he could. In a similar case Lord Denman stated it to be one of the greatest advantages of this application, that it gave a person an opportunity to come forward and deny the imputation. This case is very hard, and all the more important, as it relates to the conduct of a public functionary. On all these grounds I trust your lordship will grant a rule.

Mr. Justice Coleridge: This is a case of very great importance indeed, and if I had any doubt upon it I should think it right to ask for time to consider the affidavits; but they have been read, and it was fully discussed upon the former trial

in reference to this same inquest; I have thus a fuller knowledge than I should otherwise have had. I cannot feel surprised that Dr. Warren has felt himself much aggrieved, and has, in consequence, made this application, and that it has been a satisfaction to him to bring the facts of the case, under the notice of this court, and to have an opportunity of stating them fully, distinctly, and upon oath; and after having so done, whatever impressions have been made, and opinions taken up with before, I trust none will now remain prejudicial to his character on the mind of any person, but that every one will be convinced that he has conducted himself throughout the whole of these transactions with honour and humanity, with good will, and without any corrupt or sinister motive. He has done his duty, and his duty only, has done it with honour, and with humanity, exhibiting all that ability and skill which it is so desirable should be brought to bear on such a case, and which was to be expected from a man of his experience and knowledge.

But I have, notwithstanding, no doubt whatever that this application ought not to be entertained. It has been put by the learned counsel in a twofold shape: as a personal application by a private individual for redress of his grievances; and has also made Dr. Warren an advocate of the public, accusing Mr. Wakley, as a public officer, of a grave misdemeanour. The case divides itself into three parts: the conduct of Mr. Wakley in the investigation; in seeking to press a verdict for the jury before they were in possession of the whole case; and his conduct at the public meeting, on March 11. One cannot but see that the substance of these charges is the first. With respect to what has been alleged, no fact but the one I am about to mention was not as well known to Dr. Warren in August last as now and during the interval. Dr. Warren could not apply for a criminal information, unless it is shown that some new fact had come to light which gives colour to previous transactions. Dr. Warren has been aware of the necessity of giving that explanation, which, as I understand it, is that he did not think it proper to make application, because Mr. Wakley had taken upon him the initiative, and he felt bound to wait until such proceedings had terminated. Now, it is certain that such proceedings did not commence till Hilary term; he thus allowed Michaelmas term to go by without any notice being taken of Mr. Wakley's misconduct.

But what is the new fact which came subsequently to his knowledge? Why, it is a very serious one: an application to a party to draw up a verdict, charging certain persons with the death of the unfortunate subject of the inquest, before the jury had been placed in possession of the whole case. But, unfortunately, there is no evidence of that fact, and it therefore rests upon information and belief. The party supplying such information is not named, nor is any explanation given why that name is not furnished. I dare say that such explanation would have relieved the difficulty. The affidavit stated the name of the party to whom the application was made, but it does not say that such person will make an affidavit of the fact.

It then resolves itself into a question of belief or information, which I cannot take as the foundation of a criminal charge. It seems, then, that the case is now too far removed from the time in which the grounds of the case originated, to be taken notice of either by Dr. Warren or others.

Mr. Warren, in his address, stated that enough was stated to bring the other side to answer to the charge. I had always understood that this court puts itself in the place of the grand jury, and it cannot be stated that less evidence should be taken here than before a grand jury. I will not go into authorities now on this subject; it is a well-known rule at common law, and has been acted on continually in this court. Mr. Warren, as I understood, said that if evidence was not found to bear out the statements made at the granting the rule *nisi*, it would be dis-

charged; which, in my opinion, would show at once that the rule never ought to have been granted.

We now come to the meeting of the 11th of March, and this is to be considered in two ways: either as a misdemeanour for which a criminal information is to be granted; or as standing connected with the conduct of Mr. Wakley at and during the inquest, and bringing proof of and improper conduct or feeling towards Dr. Warren down to that time. His ground is that it points the arrow—to use Mr. Warren's expression—before directed against Dr. Warren. I have paid attention to this representation, and have since looked into the remarks of Mr. Wakley, and I do not think that was the intention, nor do I think it has had that effect, and I will not go further into it.

With regard to its being properly a subject for a criminal information I must say the application wholly fails. I agree with Mr. Warren and the learned judge whom he has quoted, that no one has any right wantonly to bring into discredit the decisions of a court of justice; and if respect is due to any court it is to the supreme court of judicature, especially as presided over by the noble and learned judge as at present. But I do not think that the Court of Queen's Bench needs the support of a criminal information to uphold its decisions, and I think it best asserts its own dignity by disregarding such comments, especially when I cannot see that there was any intention wantonly or in an offensive manner to throw discredit on the judgment pronounced. Every person who has become the subject of a judgment of a court painful to his character or property feels sore, and one cannot wonder that afterwards, if he have to speak of that judgment, that he does so as an injured man; and I think he on this occasion delivered himself with no more freedom than was allowable and natural to one in his position. I do not think he had examined the judgment fairly; nor do I think the judgment will suffer by Mr. Wakley's criticisms. So much, then, for these observations as supplying substantial grounds for a charge, or as bringing the conduct of Mr. Wakley down to the present time. As long as Mr. Wakley addresses a public meeting on this subject, which is lawful for him to do, he will believe and speak in the same manner, and I cannot think that this will make his conduct the subject of a criminal information.

This application was made on the affidavits of Sir James M'Grigor, Lieutenant-Colonel Shirley, Dr. Knox, Dr. Warren, Dr. Reid, Mr. Day, and three privates belonging to the 7th Hussars, with the addition of affidavits of reporters.

UNIVERSITY COLLEGE.

On Saturday last the distribution of prizes in the medical department of this college took place. Lord Brougham occupied the chair, and the proceedings opened with the reading of the annual report by Mr. Liston, Dean of the Faculty of Medicine. From that document it appeared that the number of medical students who attended classes during the past year was 290, the number of the preceding year being 292.

At the first examination for the degree of M.B. in the University of London, gold medals were awarded to Mr. Thomas Littleton for proficiency in anatomy and physiology; to Mr. Thomas Armstrong Cammack for chemistry, and to Mr. Joseph Burdon for Materia Medica; and both the gold medals annually conferred on successful competitors by the Society of Apothecaries were gained by students of this college, namely, the medal for botany by Mr. James Morris, and that for Materia Medica by Mr. Thos. Park.

The following is a list of the prizes awarded April 30, and the names of the successful competitors:—

Class of Medicine.—Thomas Park, of Lincoln; H. Briggs, of Halifax; J. Bailey, of London.

Class of Anatomy and Physiology.—James Morris, of London; Archibald T. Childe, of Rungby; Daniel Bates, of Sheffield.

Class of Chemistry.—H. C. Wood, G. H. Bailey, W. M. G. Hewett, J. Lister, J. R. Heynolds, and W. Payne.

Class of Anatomy.—J. W. Saunders, W. M. G. Hewett, W. Bayldon, J. Morris, C. D. R. Symons.

Class of Comparative Anatomy.—B. Bose.

Class of Materia Medica and Therapeutics.—J. Rigby, W. Squire, T. Limbery.

Class of Midwifery.—F. C. Webb, W. Bayldon, H. Briggs.

Class of Surgery.—T. Park, F. C. Webb, C. D. R. Symons.

Class of Dental Surgery.—W. Bayldon.

SUMMER TERM, 1846.

Class of Botany.—B. Bose, W. D. Wilkes.

Class of Medical Jurisprudence.—T. Park.

Class of Pathological Anatomy.—W. H. Ransom, of Cromer.

Fellowes Clinical Medal.—Gold medal, W. H. Ransom.

Prize of £40 for General Proficiency.—W. H. Ransom.

THE CLARING-CROSS HOSPITAL.

At the annual distribution of prizes to the students attending the medical school of this hospital marks of distinction were awarded by the Right Hon. Vernon Smith to the following gentlemen:—

Surgery.—Junior Class: Bronze medals, G. M. Young and J. W. Paternoster; certificate, F. W. A. Rawlins. Senior Class: Silver medal, C. R. Durell; certificate, J. Buckstone.

Materia Medica.—Silver medal, C. Terry; certificate, C. Wood.

Practical Anatomy.—Junior: Bronze medal, C. Terry; certificate, C. Wood. Senior: Silver medal, J. Fayer; certificate, C. R. Durell.

Midwifery.—Junior: Bronze medal, G. M. Young; certificate, M. Todd. Senior: Silver medal, J. Buckstone; certificate, C. R. Durell.

Physiology.—Junior: Bronze medal, C. Terry. Senior: Silver medal, J. Fayer.

Medicine.—Junior: Bronze medal, G. M. Young; certificate, G. W. Paternoster. Senior: Silver medal, C. R. Durell; certificate, J. Buckstone.

Chemistry.—Silver medal, C. Wood.

Botany.—Silver medal, S. Ludlow.

Forensic Medicine.—Silver medal, J. Buckstone; certificate, A. Butler.

Clinical Prize.—Silver medal, J. G. Green.

General Proficiency.—Gold medal, C. R. Durell; silver medal, C. R. Durell.

Two gentlemen received honorary testimonials for diligence and good conduct.

ST. GEORGE'S SCHOOL OF MEDICINE.

A public distribution of prizes awarded to the students of the School of Anatomy and Medicine adjoining St. George's Hospital took place on Saturday, the 1st inst., Sir James Clark, F.R.S., in the chair.

The Hon. Secretary (Dr. W. V. Pettigrew) read the report, giving a slight sketch of the history of the school, from its establishment by Dr. Wilson and Mr. Lane in 1830.

The prizes and honorary certificates were thus awarded:—

Anatomy and Physiology.—Mr. T. Webb, Mr. A. Brown (equal), silver medals; certificate, Mr. C. H. Payne.

Junior Anatomy.—Certificates, Mr. R. E. Price, Mr. Turner, Mr. Finimore, and Mr. H. Brown.

Clinical Medicine.—Prize, Mr. T. S. Gundry.

Clinical Surgery.—Prize, Mr. Symes.

These prizes are given by the lecturers at this school to all students entering to St. George's

Hospital practice, irrespective of the school at which they may have studied.

Medicine.—Prize, Mr. R. E. Price.

Surgery.—Prizes of equal value, Mr. P. Allen, Mr. T. Webb; certificate, Mr. R. E. Price.

Chemistry.—Prize, Mr. W. Bloxam.

Materia Medica.—Prize, Mr. W. Bloxam; certificates, Mr. G. Fast, Mr. R. E. Price.

Midwifery.—First prize, Mr. G. Jago; second prize, Mr. C. H. Payne.

Medical Jurisprudence.—Prize, Mr. Marley; certificate, Mr. Parnell.

Botany.—Prize, Mr. W. Bloxam.

Practical Chemistry.—Prize, Mr. F. Godrich.

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen were admitted members at the meeting of the Court of Examiners on Friday evening last—viz., Messrs. John Henry Walker, Dublin; Theodore Sheldon Turne, Worcester; John William Williams, Southwell, Nottinghamshire; William Johnson, Leeds; James Lardner Green, Holywell, Flintshire; Robert Stead Jones Stevens, Ely, Cambridgeshire; Alfred Adney, Exeter; Michael McDonnell, Randalstown, county of Antrim, Ireland; Henry John Barrett, Commercial-road; and Wm. Hyde Cooke, Stockton, Worcestershire.

APOTHECARIES' HALL.—Gentlemen admitted members April 29:—John Robert Humphreys, Richard Eliot West, George Goforth Wyer, John Sebastian Helmcken, Richard Thomas Smith, Thomas Stillman, and Henry Fisher.

NAVAL APPOINTMENTS. Surgeons: Charles K. Nutt, to the *Excellent*; Augustus Slight, to the *Growler*; J. W. Elliott, superintendent to the *Joseph Sommes*, convict ship; Edward T. Dickson, to be Admiralty Surgeon and Agent at Jersey. Assistant Surgeons: George Everest, to the *Kestrel*; James Peters, to the *Victory*.

ASSERTIONS.—Mr. Wakley, in the House of Commons, on Wednesday evening last, stated that, if the bill which he had introduced for the better regulation of the medical profession was not successful, he would trouble himself no more medical bills. The value of this assertion may be estimated by that of the following, made in the Queen's Bench by the Attorney-General, Jan. 30, "that the continued exercise of the office of coroner by Mr. Wakley depended upon the granting of that rule."—*Rule refused.*

DURHAM UNIVERSITY.—Several cases of acknowledged fever having occurred in Durham, the warden and senate of the university have deemed it expedient to take a medical opinion upon the subject. After due inquiry, it was determined that it did not seem requisite to disperse the members of the university, but that if the immediate friends of any student were desirous that he should be removed from the university for a time leave would be given on due application, and every facility afforded to alleviate the inconveniences which may arise. Some of the students have availed themselves of this permission; but all the lectures are proceeding in the regular manner.

WASTE OF MANURE.—"I shall say nothing of the liquid manure which, as I have been given to understand, is suffered to drain away into the ditches, thence into the rivers, and from them into the sea, from fully one half of all the home-steads of England; I will speak merely of the unappropriated refuse of large towns. In Flanders, where manure is carefully collected, instead of being, as here, suffered to run to waste, the excreta of an adult is valued at £1 19s.; considering the enormous additions made to this manure in our towns, it will not be thought unreasonable to estimate the value of that part of the refuse which now runs to waste at £2 per head of the population; and supposing that, in England or in Wales, the towns which are guilty of this extravagance contain in all only 5,000,000 inhabitants, we shall have an annual waste of at least ten millions of money." Mr. Smith, of Deanston, also expressed his opinion that,

"taking a general view of the subject, we may assume a clear revenue of the sewer-water of all towns of £1 for each inhabitant." Dr. Arnott said that "the value of town manure might be estimated by the fact that a portion of the drainage of Edinburgh has increased the value of these lands by more than £5,000 a year, and that if the whole drainage of London could be saved, at a sufficient distance from the town, the value would exceed £600,000 a year." Dr. Arnott observed that Mr. H. J. had benefited to a great extent by the adoption of such measures as he suggested; and he then went on to say that "it has been calculated that, whereas the cess-pools cannot be emptied by nightmen for less than seventeen shillings a year, and whereas water-carriers get a halfpenny for a pailful of water at the door, an addition of twopence to the rent per week will suffice for the expense of water-closets and of an unlimited supply of water for every house; and that the entire sanitary purposes contemplated under all the recommendations of the Health of Towns Commission may be procured for threepence halfpenny a week per house." These calculations might be looked upon as sanguine, but those persons who were best acquainted with the subject knew that much was to be done with regard to economy by adopting efficient sanitary regulations.—*Lord Morpeth's Speech.*

OBITUARY.—At 238, Canongate, 14th ult., Mr. William Snodgrass, surgeon.—At Alloa, 22nd ult., Dr. Russell.—At Lochgilphead, Argyleshire, 21st ult., John Wright, Esq., M.D., much and justly regretted by a wide circle of friends, amongst whom he practised successfully for many years, but more particularly by the poorer classes, to whom his kindness, whether in a pecuniary point of view or in his professional capacity, was always cheerfully and liberally bestowed.—April 19, at his residence, Sans Souci Villa, Entrehill, Bath, aged 78 years, John Gray, Esq., for more than half a century a practising surgeon in that city.—April 23, at his residence, Oakhills, near Taunton, Henry Sully, Esq., M.D., Surgeon Extraordinary to the King of Hannover.—On the 4th inst., at Tottenham, John Ramsbotham, Esq., M.D., formerly of Broad-street-buildings, in the 80th year of his age.

MORTALITY TABLE.

For the Week ending Saturday, May 1, 1847.

Causes of Death.	Total.	Average of 5 Winters.
ALL CAUSES.....	983	914
SPECIFIED CAUSES...	981	900
Zymotic (or Epidemic, Rndemic, and Contagious) Diseases.....	148	166

SAMUEL COOPER, Esq., F.R.S.

Professor of Surgery to University College, London,
Consulting Surgeon to London University Hospital, &c.

LECTURE V.

At the conclusion of my last lecture I was speaking of the buffy coat, or, as it is sometimes called, the inflammatory crust which is usually observed on the blood abstracted from patients suffering from inflammatory diseases. The buffy coat bears a striking resemblance to size; and the blood is often said to be *sizey*. In many instances such contraction of this buffy coat takes place during the coagulation as to raise the edges of the clot, and render the surface of the conglutulum concave, and then the blood is said to be cupped. In cases where the buffy coat is thick, the texture of the subjacent crassamentum is proportionately loose, as if the greater portion of the fibrine which gives firmness to the crassamentum were collected at the surface of the clot. In inflammatory diseases it would appear that there is a strong tendency in the blood to throw off its fibrinous matter; and we see this both in the body as well as out of it: large quantities of coagulable lymph being thrown out in the cavities of serous membranes, or into the cellular tissue of other parts. The buffy coat forms on the arterial as well as the venous blood in cases of inflammation, as in blood taken from the temporal artery, where from any circumstance there has been an objection to taking this fluid from the veins. Dr. Tweedie was the first to observe this fact. We do not very well understand the process by which the buffy coat is produced. Mr. Hunter explained its formation in the following manner:—He attributed it to the slowness of coagulation of inflammatory blood, which allowed time for the more complete subsidence of the red globules, which are the heaviest part of the blood, and this more complete subsidence allowed a layer of fibrine to collect at the surface of the clot almost free from globules. A strong objection, however, may be raised to this explanation, that, if it be true, we should always find more or less of the buffy coat on healthy blood, inasmuch as time is required for the completion of the coagulation. The buffy coat is absent also in all those cases where the blood does not coagulate after death, as is the case in animals which have been chased to death, in those killed by lightning, or by a sudden and severe blow on the stomach. In these cases we do not find any buffy coat, although ample time is allowed for complete subsidence of the globules. Hence we may infer that mere slowness of coagulation affords but an imperfect explanation

of this phenomenon. The buffy coat demands considerable attention from the surgeon as well as the physician, because it yields, to a certain extent, evidence of the existence of inflammation, and affords an indication for the further employment of bloodletting and other antiphlogistic measures. It will excite some surprise, that there should be any doubt of the existence of inflammation, when you take into consideration the signs of this affection I have heretofore noticed; but the detection of inflammation is in some cases by no means an easy matter, especially when it attacks deep-seated parts, where it is entirely out of the reach of ocular or manual examination. The results might be serious if we mistook inflammation for some other affection requiring an opposite plan of treatment: for in some cases our decision on the propriety of bloodletting may affect the very life of the patient. Experience will soon convince you that this is a fact.

It is necessary that I should now explain to you how far the presence of the buffy coat may be depended on as indicative of the existence of inflammation; and, in commencing your future practice, you will discover how important it is to have some guide to the use of the lancet in this disease. The doctrine that the presence of the buffy coat is an indication for bleeding, must be taken with some limitation: for, although it is a fact that the blood of patients suffering from inflammatory disease is usually buffed, yet it often occurs where no inflammation exists, and where you would do wrong to bleed your patient to any great extent, or even at all. Slight blood occurs in some cases of fever, and also in some nervous affections, when the pulse does not rise above the natural standard. Again, the buffy coat may be altogether absent where severe inflammation really exists. The concomitant symptoms must, therefore, be attended to: the amount of fever, the frequency of the pulse, the nature and situation of the pain, and the general functional disturbance, are points of great importance in establishing our diagnosis, and the indications founded upon it. These considerations, taken conjointly with the state of the blood observed in the first bloodletting, will usually enable us to form a correct diagnosis of the disease, and the amount of its severity.

It has been asserted by some practitioners at Edinburgh, that, although the blood presents no buffy coat in some cases of inflammation, the cupping of the conglutulum affords a constant sign of the presence of inflammation. I am induced to think that the cupped state of the clot is a corroborative sign of the presence of inflammation. In some doubtful cases it may be prudent to take away a few ounces of blood, which can do no harm to the patient, and will give additional certainty to our opinion of the nature of the disease. In cases of deep-seated inflammation, where the signs are somewhat doubtful, our opinion must be based on an examination of the

amount and kind of symptomatic fever, as ascertained by observing what functions are disturbed, and noticing whether the blood is buffed, and whether it is cupped. Inflammations of internal or deep-seated parts may be attended by the usual effects of inflammation, and produce swelling, redness, induration, suppuration, mortification, and others of its less frequent results. These are discovered in the *post-mortem* examination of the patient, although they may not have been discoverable during life. In a former lecture I told you that heat, redness, swelling, and pain were the ordinary symptoms of inflammation, although the whole of these might not be present in a particular case. We must not, however, rest satisfied with the knowledge that these are the usual signs of inflammation; we must investigate their causes. Redness, then depends on a dilatation of the capillary vessels of the part, which are so increased in diameter as to allow a much larger quantity of blood to accumulate in them. They are, however, not merely dilated in a passive manner; they are positively injected with blood, there is an excessive turgescence—a vascular congestion or hyperemia, as it is called by Andral. Some theoretical writers on inflammation have supposed that the minute arteries were affected with spasm, and constricted so as to force the blood in larger quantities into the minute veins, which, being dilated, render the part redder and more turgid. A serious objection to this theory is, that we are unable to determine where the arteries terminate, and the veins commence. It was the opinion of the celebrated John Hunter, that in some instances new vessels were produced, and that some portion of the redness might be accounted for by that circumstance; but this cannot frequently occur. Parts which are in their natural state colourless may be strongly reddened by minute anatomical injection; and this proves that the dilatation and turgescence of the capillaries may cause preternatural redness, by admitting a much larger supply of blood than under ordinary circumstances. Tendons and other parts which are not naturally red become coloured by inflammation. In the healthy condition you cannot produce redness of a tendon by the finest anatomical injection, but when a tendon has been inflamed, the injection penetrates vessels which are naturally too small to admit it, and the tendon is easily reddened. Many vessels which, from their minuteness, are not visible in the healthy condition of the part, are so much dilated by inflammation as to become visible, and hence the doctrine, that new vessels are formed during inflammation, must be received with great caution. A very common result of inflammation is the destruction of the transparency of the parts. This change is readily observed in the inflammation of the arachnoid and other serous membranes, which, from being transparent, become perfectly opaque when inflamed. This change,

common to all serous membranes as well as the transparent tunics of the eye, is brought about by the deposition of coagulable lymph either on their surface or within their texture. A preparation, still preserved in the museum of the College of Surgeons, shows the effect of inflammation in destroying the transparency of a part subjected to its influence. Mr. Hunter froze the ear of a rabbit and then thawed it, after which the ear became strongly inflamed. While in this state the rabbit was killed, and the vessels of the head injected. The two ears were dried, when it was found that the healthy ear became quite transparent, and its vessels of a natural size, while the inflamed ear was opaque, thickened, and otherwise enlarged.

Swelling, another of the signs of inflammation, is caused by the greater amount of blood in the part as a result of their dilatation, and by the effusion of coagulable lymph into the surrounding cellular tissue. In inflamed parts the action of the absorbents appears to be diminished or altogether interrupted, which may have some influence in increasing the swelling.

The sensation of heat in an inflamed part, of which patients so grievously complain, is usually much greater than the actual rise of temperature as shown by the thermometer. The fallacy of our sensations, as a measure of heat, is equally observed in cases of fever, where, judging from the dry and hot skin, we should imagine that the heat was considerably raised above the natural temperature; but, when we apply a thermometer, we find that the utmost increase is five or six degrees. Mr. Hunter made some experiments to ascertain the actual increase of heat in inflammation. He produced inflammation in the chest of a dog, and in the abdomen, rectum, and vagina of an ass, but was unable to detect any rise of temperature. In a patient who had undergone the operation for hydrocele the heat increased from 92° to 98½°. Some authors have attributed the increase of heat to greater velocity of the circulation; but this explanation cannot be received, because the same increase of temperature has been observed in a patient whose pulse was not more than forty-five in the minute. Moreover, the current of blood in the capillaries of the inflamed part is now well known to be slower than in the healthy condition.

The pain of inflammation has been attributed to increased sensibility of the nerves of the part; the unusual circumstances in which they are placed; the changes taking place in the inflamed part to which they are distributed, or to inflammation of the nervous fibrillæ themselves. To which of these, or indeed to what cause, we must attribute the pain is extremely uncertain, and I shall not lose time in discussing these speculative questions. Throbbing, which is a frequent accompaniment of inflammation, is attributed to the strong pulsation of the arteries. It was the opinion of John Hunter, that not only the arteries in the inflamed part, but also those leading to it, pulsate with increased vehemence. In whitlows, for example, the radial and ulnar arteries beat with increased force, and this force he attributed to their unnatural dilatation. The first act of inflammation is compared by that celebrated physiologist to a blush, after which a new action is set up, followed by an effusion of coagulable lymph and serum, which produces the tumefaction so often observed around an inflamed part. Serous membranes are the parts, as I have already remarked, that are most liable to adhesive inflammation. When inflamed, they throw out coagulable lymph with equal ease and rapidity, which after some time becomes organized, and converted into bands of cellular tissue. The radical cure of hydrocele depends on this property of serous membranes; and the coagulable lymph which glues the surfaces of the tunica vaginalis together subsequently becomes organized. Adhesions of the pleura pulmonalis to the pleura costalis, of the investing with the reflected pericardium; of the intestine to each other and to the peritonæum, are the consequences of the effusion of coagulable lymph. In pa-

tients who have died of pericarditis we find the heart covered with a layer of this coagulable lymph, which in some cases produces universal adhesion of the pericardium to the heart. Lymph is in like manner effused on the serous surface of the dura mater, between the layers of the arachnoid; while in rarer instances it is deposited on the surface of mucous membranes, as in croup and other forms of laryngitis.

Another result of inflammation is preternatural hardening or solidification of parts. Thus in pneumonia the lung becomes as hard as the liver, and is said to be hepatized. When tumours press upon parts, the exposure of which would be dangerous to life, thickening is produced instead of absorption, the usual result of pressure. Thus in cases of internal aneurism, when the bursting of the aneurismal sac would be attended with fatal consequences, thickening of the superjacent parts is produced until, by the increase of the pressure corresponding with the increase of the tumour, these parts can no longer resist its ordinary influence, and an opposite action is then induced—that of thinning or atrophy.

Mucous membranes, as I have demonstrated to you, sometimes throw out coagulable lymph; but in such cases the inflammation is of a peculiar and violent character. Here is an inflamed bladder which is lined by a layer of lymph which has exuded during the course of the inflammation. The inflammation was induced by the extreme irritation produced by stricture and retention of urine. There is this difference between effusions of lymph on the surface of serous membranes and into the cellular tissue, that in the former case the lymph remains and becomes organized, while in the latter it is after a time absorbed and disappears. When during the process of organization of effused lymph it becomes vascular, the vascularity is not produced by the formation of new vessels, but by the prolongation of the original vessels of the tissue into it, extending into the lymph like the roots of plants in the soil.

Inflammation is always most violent near the surface, as if it had a constant tendency to spread outwards. Inflammation induced by a decayed tooth, for example, produces inflammation of the surrounding gum, which is almost always confined to the outer side nearest the cheek, which in its turn becomes swelled and inflamed, while the inner side of the gum is but little affected. It would seem that this spreading toward the surface is one of the laws of inflammation; and the utility of this law is frequently very evident, for when we have extraneous bodies or collections of matter in the body, if the inflammation were to spread inwards, the probability of mischief would be rendered much greater, and the chances of cure more uncertain; but, as the inflammation tends towards the surface, it produces changes which end in the expulsion of the offending substance.

The causes of inflammation are divided into proximate and remote. The remote causes are again subdivided into predisposing and exciting. The human body has a natural tendency to inflammation, for if this were not the case, there would be no chance of recovery from certain injuries and diseases; and in this light inflammation may be considered as a salutary process. Moreover, certain constitutions have a greater tendency to inflammation than others, and this disposition to inflammation we term the inflammatory or phlogistic diathesis. Such a state of the system may be innate or acquired. In the latter case it is dependent on the habits of the individual, or on the application of particular predisposing causes. The most powerful of all the predisposing causes of inflammation is plethora, produced by excessive eating and drinking. The practice of high living, generally accompanied by indolence, produces an inordinate quantity of blood, which distends the vessels, and renders the individual more liable to inflammation, and the inflammation itself more difficult to remove. This circumstance is observed in porters and draymen, who

consume large quantities of alcoholic drinks, which induce a plethoric state of the system, and at the same time render them very bad subjects for inflammation. These men appear to the common observer in the most robust health, but let them be the subjects of slight injuries, and inflammation follows, of a kind which is almost invariably fatal, and from which persons of temperate habits would suffer comparatively little inconvenience or danger.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILLSHIRE, M.D. (Edin.), M.B.S.,
Physician to the Royal Infirmary for Children, &c. &c.

(Continued from p. 210.)

GENTLEMEN.—In a previous lecture, when speaking of the signs of, scrofulous disorder, whether of the inflammatory or tubercular character, I necessarily indicated some of the symptoms of the general malady; but I have yet to draw your attention to some of the more particular ones of tuberculization itself. Of course you will at once perceive that, from tubercular disorder being liable to attack such important organs as the lungs, brain, mesenteric glands, the larger joints, &c. &c., the symptoms indicating the affection will vary extremely in the different cases, according to the structure or organs in which it is going on, or the amount of its diffusion, and as to whether there be intercurrent inflammation, and of what grade, and also according to the metamorphosis the morbid deposit itself undergoes. The symptoms and diagnosis, therefore, of tuberculous disease of the lungs, brain, &c., I can only speak to you about when I shall happen to treat specially of phthisis, hydrocephalus, &c., and shall, therefore, at present bring before you notice some very general symptoms only. As a general rule you will find that—beyond the symptoms I have already alluded to—emaciation, debility, and fever are the three chief phenomena by which the progressive development of tubercle is mostly accompanied. With these, of course, exist symptoms of a local character having special relation to the organs or structure most severely attacked. Emaciation is certainly one of the most constant and prominent features of the progress of tuberculization; and although you may find children, between the completion of the first and of the second dentition, die with very general deposit of tubercles, and yet without much emaciation, yet, before and after that age, extreme emaciation is seen as the general rule. When severe tuberculization is going on, and there is no emaciation, or at least not much, then the disease is generally very acute in its attack; but, on the other hand, emaciation does not often follow when there is simply chronic tuberculization of the contents of the cranium. If a child above four or five years of age becomes evidently emaciated, and this loss of flesh has not quickly supervened upon the decline of an acute malady, but has been present for some little time, you should direct attention to it especially. When emaciation has gradually obtained a certain point, its after progress is often very rapid; and, if diarrhoea sets in, the loss of flesh is seen to be extreme—children often being reduced to mere skeletons. Here, of course, we have superadded, loss of appetite, diarrhoea, affections of the mucous membranes, colliquative sweats, hectic fever, &c.

Debility is another very early symptom. Long before any discharges are present, or colliquative sweats, and even the digestion often good, and no febrile exacerbation, the little patient feels weak, gets thin, and makes "no way." There is a gradual disinclination to mix in the usual sports, at first when more than common exertion is required; afterwards, it will remain constantly quiescent. In some cases it is true, however, that you will find children who suffer under very general and intense tuberculosis, and yet are able to go about until almost the day they die.

I remember a case I had of a boy whose mother was obliged to lock the doors and windows, to prevent him running about in his nightshirt when she happened to leave him. One day, the day before he died, she went out, fastening the door of his bedroom, but not the window. He attempted to get out at the open window, alarmed the neighbours, who immediately spread reports as to the *crudelty* of the mother, and a coroner's inquest was the result. The tuberculosis in this boy was very general, and his brother died under my care a few months afterwards of the same disease. I may remark that in both of these patients the development of hair over the body was remarkable, so were their ravenous appetites and ptyhmatous eruptions. Still, in most cases, you will find the depression of power gradually increase until the slightest movement becomes too much to execute. The mother constantly tells you she has brought you her child because "he gets so thin and has no more strength than if he was a baby." Whenever you are told such a story, attend anxiously to such a boy, and be careful to examine for the general and artistic characters of the scrofulous tendency.

In young persons, even on the first approach of tubercularization, some degree of fever may be said to be present. The type of this fever is subcontinued or remittent, but of course varies in its periods, intensity, and amount of exacerbation, according to contingent circumstances. Once established, whenever it may come on, its course is onward, with a gradual and regular increase of symptoms, and *hectic* becomes established. The perspirations, diarrhoea, emaciation, and debility, become all extreme; but still the amount of the former two vary according to the organ or structure more intensely attacked, or the integrity of which is more essential to the patient.

Serous effusion, I may also notice, as being amongst the less universal accompaniments to tuberculous disorder, although in one particular form it is pretty constant: when the brain is invaded by scrofula, either *primarily* so, or as contingent with the deposit elsewhere, effusion into the ventricles is a frequent phenomenon, and constitutes one of the forms of the important affection—hydrocephalus; sometimes there arise oedema or anasarca of the face or extremities, or effusion into the larger cavities.

I do not think it worth while to detain you with any theoretical disquisitions on what has been called "strumous dyspepsia" and "dyspeptic phthisis," nor with any notice of the conditions of appetite, pulse, tongue, rest, &c.:—this last category of symptoms being easily reasoned upon by you, from the knowledge you already possess of the general principles of medicine.

Important as you will find these three phenomena—*emaciation*, *debility*, and *fever*, and justly guiding you to investigate narrowly their causes, yet they may neither of them be presented to you in sufficient intensity to become prominent enough to be taken notice of, but still the child or youth will evince something is going on very wrong. He may not be very weak, thin, or fevered, and yet present you with warnings of vast importance. These warnings may be comprised in what is understood by the French writers as the feeling of "*malaise*," "*de moins bonne disposition générale*," occurring in a child of from ten to fourteen years of age, of the scrofulous diathesis. It is a kind of vague, general morbid condition—a sort of continual oscillation of health betwixt a very doubtful or incomplete and insufficiently pronounced state of malady. The phenomena of which this *malaise* is made up are at first very irregular in their occurrence, the child getting better and worse, worse and better, for some length of time, until at last—if proper hygienic measures have not been had recourse to, or too often, alas! if they have—this feeling of *malaise* gradually gives place to a distinct and easily expressed one of complete illness. We have, then, loss of flesh and power, and febrile crathism is superadded, with what has been called by Fournet an "*expression de travail ou de souffrance organique*," which is not

an expression of pain, but a sort of reflection of feeling instinctive of the gradual deterioration of the body. Now, whatever may be the signs or symptoms by which tubercular disorder is made known to you, of course they will vary in intensity and degree as well as in rapidity of progress; and upon such variation depends what may be called *acute*, *chronic*, and *latent* tuberculosis. The general character of the first, or acute form, is, that it is accompanied from the outset with febrile excitement of considerable intensity. This fever is also broken into periods, less remitting, than is usual—it is more continued, and sometimes of a very low type; nothing, also, can be gleaned from it as to where the tubercular disease is going on, or how great is its diffusion. Soon, however, you will find that certain local symptoms will be presented to you—cough, dyspnoea, &c.—indicating that the respiratory organs are suffering; or vomiting, constipation, cephalalgia, and finally coma, indicative of the meninges being the parts involved. Until these local symptoms supervene, the true nature of the disease is very liable to be overlooked. Tubercularization of the meninges is the most rapid form of the disorder that I know of.

The *chronic* form is the one most frequently met with, but still not such a *prolonged* chronic form as we meet with in adults. The younger the child the less chronic does it usually appear. In certain cases this form is liable to be confounded with other maladies. Of its symptoms I have already spoken, and therefore need say nothing further here.

The term "*latent tubercularization*" has been rather indefinitely applied. For instance, it has been made use of to imply cases in which no general symptoms or constitutional signs are very evident, nor any local ones either, and yet the disease be making considerable progress; or, again, it has been applied to instances in which the constitutional symptoms appear long before any local ones. Others employ it to express the disease not making itself known by either the constitutional or local signs usually attendant upon it, and yet the fatal event be certainly induced by it, the patient all this time, however, having been known to be labouring under tubercularization of other organs of the body. For instance, a child exhibits the usual symptoms of disease of the mesenteric or bronchial glands, but you find no reason (from the want of appreciable symptoms) to believe it suffers under tuberculous meningitis, yet a day before death it is slightly convulsed, or partially paralysed, and upon inspection evidences of the latter disease are seen. Other modes of applying this term also have been followed, more especially in relation to adults. In many cases of latent tubercularization of a special organ in children the "*latency*" of it is partly owing to the patient labouring under severe disease of some other structure, which by the prominence of its symptoms masks those of the former. But there are cases in which such does not hold good: the disease is overlooked on account of the slight degree of its symptoms, attention not being paid to the organ really at fault, and the child does not labour under any other severe disorder. I have already told you about latent peritonitis, as also of latent forms of tuberculosis of the mass of the brain itself, and shall have more to say upon these points hereafter.

Before passing on to the consideration of the treatment of scrofula, I have yet a few words to say upon some portion of its pathology. You know that, in reasoning upon the nature and cause of any disorder, we generalize as much as we can, and when we have done so, we accept the facts developed by the most extensive generalization as the most ultimate laws we can attain to, and build upon them as our foundation in our theory of the special disease. Generalize and extend our analysis of phenomena as far as ever we like, however, there always will remain a phenomenon beyond which we can no further proceed, and any attempt at explanation of such a phenomenon will be either a venture of

a mere hypothesis, or else one unguided by the principles of common sense. It will ~~never~~ be between one and the other according to the amount of possible or probable data to go upon, and their entire want in the opinions of those generally held to be the better able to judge.

As regards the most fundamental law we can attain to in scrofula, it is that there is a diseased state of the blood. We may express this in other terms, or attempt to indicate the nature of the diseased state, but then, I fear, we dive into hypothesis. As to the why and wherefore, also, of this diseased or abnormal condition of the circulating fluid, we can only offer very general opinions. Some, it is true, seem to bear very closely upon the subject in question; others, again, have evidently but a very vague and distant connection with it. You know that the nature of the components of the blood may depend either upon that of the digested matters taken up by the lacteals from the surface of the digestive tube, or on the after actions exerted upon them in the absorbent system, or upon both. The nature of the digested matters taken up by the lacteals may also depend either upon the materials obtained from without, or upon the powers of selective absorption or of appropriation possessed by those structures whose duty it is to take up the proper substances from digested matters and give them to the lacteals. This state of the blood in scrofulous children, therefore, may be brought about either by improper or insufficient nutritive material obtained from without, or from their having a peculiar condition of body by which no proper assimilation can go on even when due and proper nourishment is offered to it; or both these causes, of course, may operate together. The latter statement you may think is indeed vague and indefinite—capable of all sorts of construction, and so in truth it is: when we attempt at extreme generalization in medicine, it always must be so.

I believe you may accept this as truth, however, derived from plenty of experience—that the scrofulous diathesis is transmissible from parent to offspring, and that, therefore, scrofula is hereditary. That the diseased tendency imparted to the child from the parent may be so strong, that do what you like, take all possible care both as regards hygiene and therapeutics, and all may be of no avail in saving the child, even from fatal forms of the disorder. It is equally my belief that a child may be entirely free from the least hereditary taint or disposition, but that it may be fed so badly, both as regards quantity and quality in all their relations, clothed so indifferently, exposed to such depressing powers of life—such as cold, damp, darkness, confinement—that, several of such conditions acting together, shall cause scrofula to be developed in the child so subjected to them. It is my belief, however, that in the greater number of cases the constitution is impressed with an original morbid tendency; but I cannot for a moment think of siding with the extreme opinion of Lugol, that scrofula must always be transmitted. You can readily imagine what must be the result, when, as often amongst the poor, both the hereditary taint and long-continued though mild, or temporary but intense duration of the vital depressors I have alluded to are conjoined together. I am of opinion that bad or insufficient food alone will give rise to scrofula in a child, not hereditarily affected, in particular instances; but usually it must be, and generally is, conjoined with several other depressing circumstances.

That mode of life and state of circumstances which force the parent to bring up her offspring in bad or deficient food, in nine cases out of ten, also involve deficient means of protection from cold, wet, and other climatorial changes; and to which, again, are often unnecessarily superadded long-continued confinement in infant and public schools or charities, vitiated, pent-up atmospheres, and noxious influences of a like kind.

In children hereditarily tainted, but yet not evincing any symptoms of tuberculous deposit, an attack of measles and smallpox frequently is followed by irruption, either of the inflammatory

form of the general disorder, its tubercular, or both. Some persons think so of hooping-cough too; but, in fact, any disorder which has been severe, and reduced the vital energies considerably, is liable to induce the often rapid evolution of scrofulous disease in children like the above. Such children might have escaped altogether unless these disorders had occurred. I have seen typhoid fever in several instances the pioneer to the scrofulous disease—a type of fever, let me tell you, more common in children than is generally supposed. The constitution tainted with syphilis from the parents, and subjected to the vital depressors I mentioned to you before, will soon run into scrofula; and where the two are bestowed at once by the parent, woe be unto their children, for there is no logworse.

There is one point I must not forget; it is this—can a sound constitution, suckled by a scrofulous wet-nurse, be so made scrofulous? I think it can, but not by the milk containing a scrofulous germ in it, and so given to the infant, but by its simply answering to the doctrine I have before laid down, that bad nourishment will bring about such a weak, defective state of body that, on the exposure of the latter to other vital depressors, the general malady will make its appearance. It is true that in those cases in which wet-nurses are employed the other depressors are not so likely to be added, because they occur in the better ranks of life; but, when the constitution is ruined so early in the child, it often requires little else to effect the purpose alluded to, save the fundamental one I speak of.

It may be asked also, is scrofula contagious—infectious? Neither, I believe, though I am not ignorant of some experiments made on the lower animals to prove it to be so. You may know, also, that it is not an uncommon belief that persons can “catch” consumption from another; and I remember to have remarked it was a very prevalent opinion in the north of Africa, when I was there some few years ago. They would not have allowed a tuberculous child to have slept with a healthy one, in case it might have imparted the disease. I believe, also, this notion is more prevalent in warm countries than in cold. But, however right it might be, and certainly is, to prevent such close contact, it is not from fear of infection of the particular malady.

Certain articles of diet—*pork*, for instance, has been said to induce scrofula. It may in this way: *pork*, in its various forms, is generally composed of as much fat as lean, which of course will make a bad article of food for any continuance, and the *lean* of *pork* itself is not the best meat to eat for any length of time; but whenever *pork* in its various forms is the general article of meat, in the greater number of cases some of the other depressors I have often spoken of are in operation too. A constant vegetable dietary has been considered very bad by one party, whilst another appeals to warm countries, and says it is the best. In high latitudes it is, in my opinion, detrimental in the extreme. In a cold, damp, variable climate like our own, the want of animal food is a constant exciting cause of the irruption of the various forms of scrofula.

I shall, having so long detained you on the pathology of scrofula, in my next lecture pass to its treatment, hygienic and therapeutic; and from what I have to say upon the former you will be able to glean something more as to the causes of this devastating malady.

ORIGINAL CONTRIBUTIONS.

A STATISTIC AND CRITICAL REPORT OF THE EFFECTS OF ETHERIC INHALATION, FROM CASES RECORDED IN THE HOSPITALS OF PARIS.

Translated from the Original of Dr. BURGHIÈRES.

(Continued from p. 198.)

The principal points we now propose to examine relate to the period of time during

which the etheric inhalation has been continued; to psychologic phenomena; to the sensitive and motive powers; to the operation of the etheric intoxication; to the phenomena which occur at the time of waking; to the system of etherization hitherto applied to surgical operations, and their consequent phenomena.

DURATION OF ETHERIC INHALATION.

The time during which the etheric inhalation has been continued varies from a few seconds to thirty minutes. With some patients the collapse and most complete insensibility have been produced by five or six inspirations; in other cases the sleep has been imperfect after inhalation for half an hour. These differences may have resulted, particularly in the earlier experiments, from the method of operating; but many of them must unquestionably be attributed to the constitutional character of the patients, since the inhalation was made through the same apparatus and under similar circumstances.

Exclusion of these idiosyncrasies, the sex, the age, and certain habits, exercise a manifest influence.

Women, in general, are subdued much sooner than men: for while the average period of inhalation with the latter has been eight minutes, it has not with the former exceeded four.

Age establishes still greater differences; as we approach infancy the effects are still more rapid. M. Paul Guersant, who has operated on children under fourteen years of age, has never been obliged to continue inhalation more than two minutes, and in most cases five or six inspirations have been found sufficient to produce sleep with insensibility. This surgeon, having to perform the operation for stone on a child of only twenty-eight months old, considered it his duty to abstain from the use of etheric inhalation.

As regards habit, it is remarkable that in those individuals with whom it has been found necessary to continue for the greatest length of time the inspiration of ether, and in such instances occasionally without success, we have met with many confirmed drunkards. (One patient, whom M. Blandin could not etherize, declared that he “could drink six bottles” without being “fresh” (*sans être en train*).) Another defied the surgeon to inebriate him with ether: “It is a long time,” said he, “since brandy has had any effect on me.” Separate, however, from these cases, the number of impracticable patients has been small: since the employment of well-constructed apparatus we may estimate them at less than one per cent.

THE MOMENT AT WHICH THE INHALATION SHOULD BE STOPPED.

Surgeons are not yet uniform in their opinions as to the precise moment when the inhalation should be suspended. Some, M. Blandin for instance, think that we should stop at the second period—when the senses are lost, and the patient is no longer conscious of what is done to him, although the power of sensation is not totally destroyed.

M. Jobert goes somewhat farther—to the commencement of the third period, when the state of insensibility is complete.

Some surgeons have even gone to the last stage of the third period, and we have seen many of their patients exhibit proofs of etheric stupefaction carried to the last degree—slackening of the pulse, coldness of the extremities, difficulty of breathing, &c. This is, according to our opinion, going too far, and incurring the risk of most serious accidents. We have already observed that asphyxia may result from a protracted inhalation of the vapour. For the same reason, although we have seen it done, we should not allow the patient to be in contact with the inhaling apparatus during the whole period of the operation. It is much safer to have again recourse to the ether, should there appear a too speedy revival of sensation. This practice, of which the foreign journals report numerous examples, in addition to the three cases which have occurred in our hospitals, we recommend as the proper one to follow.

PSYCHOLOGIC PHENOMENA.

The psychologic phenomena observed during etheric intoxication will be found worthy of a special and most profound study; although a suspension of the mental faculties is the general effect of ether, we notice sometimes the integrity of all these faculties, or perhaps one alone of them. In this last case etherization may become a curious means of psychologic analysis.

We have seen some patients, notwithstanding the etheric influence, enjoy a free exercise of their intellectual faculties; converse with the operator, to a certain extent assist him, and, remarkable as the fact may appear, although they retained their intellectual faculties undisturbed, the powers of sensation were not less completely extinguished. These extraordinary phenomena have occurred three times to our observation.

But we more frequently discover a singular perversion of the intellect—sometimes, in fact, a perfect delirium. In this case the excitement which is usual during the first period continues or goes on increasing in proportion to the supply of etheric inhalation; nevertheless, the patients continue calm, and the disordered state of their ideas is developed by certain incoherent expressions. This delirium assumes in almost all cases a cheerful character: in two only has it presented the form of furious madness.

Patients do not betray the mental occupation during the time or period of etheric intoxication; it is, in fact, when the slumber ceases that they relate their dreams, and recognise those sentiments which an active imagination had created during the stupefaction of every other faculty. But the most remarkable occurrence we met with is this:—The imaginations of their delirium, whether accompanied or not by declaration—(a) their dreams, whether influenced by the pineal gland or the mind, have, in every instance, been perfectly unconnected with the operation.

If amongst those operated on there are any who complain, it is he who, because he is unfortunate, laments that he is born to sorrow; another, that his rights of participation are contested; this one, concerning some gambling dispute or the jockey, because his horse has been stolen. There has not, however, been one instance in which these patients were not relieved from such an amount of moral anguish as the painful preparations of a surgical operation, and the different details of its accomplishment, do not ordinarily produce. As to dreams of an agreeable character, they have presented a diversity of form more or less vague: one patient contents himself by declaring that he was “perfectly easy;” another, when he revived, gave a poetical description of the enchanted countries he had traversed; a woman believed she had been with God and his angels. On two occasions only with women have we found revealed those (*erotiques*) dreams upon which M. Majendie has so much insisted; and in these two cases there did not transpire the slightest violation of modesty. If, however, the learned physiologist should find that these two facts justify his criticisms, what will he say upon, the case in which a mother, suffering from an immense inflammatory tumour of the breast, and being interrogated as to the satisfaction she had evinced at the moment when, under the influence of ether, several incisions were made by the knife, replied that she “experienced the delightful sensation of her infant relieving her swollen breast of the milk.”

The examples we have recorded of dreams and delirious conceptions are sufficient to give some idea of the influence which ether may exercise over the intuitive phenomena by a momentary suspension of soul, without paralyzing its accessories.

Ether produces on the memory an impression the most certain and uniform. Whatever may

(a) This sentence in the original is curious; it runs thus:—“Quo les rêves aient été sensoriaux ou psychiques.”

have been the condition of the other faculties during the etheric sleep—to whatever degree the power of sensation has been affected—there is not on record one single instance where the patient has preserved any recollection of what has been done to him. As regards the question of memory, there has also been remarked a most singular evidence of the concentrated action of ether. It sometimes occurs that the operation itself, whatever relates to it, and the pain which it might occasion, are entirely unknown to the patient, although he remembers with precision every other circumstance which has passed around him—the thoughts which have occupied his mind, and the dreams which he has had; but in almost every instance, and even where signs of sensibility have been given, he declares that "he has felt nothing—that he is unconscious of having been operated on."

THE STATE OF SENSIBILITY.

The extinction of sensibility constitutes the most important result of etheric inhalation; it is this property which has excited so much attention, and by its accessorial aid has been adapted to the performance of surgical operations. The sense of feeling is not always affected in the same manner or in the same degree. From the declaration made by the greater portion of those operated on, that they have not experienced any suffering, it is generally admitted that there is in reality a total absence of pain; nevertheless, in many cases, the patient is agitated, and cries out when the operator applies the knife. These are evidently signs of agony. It is true, however, as we have seen above, that no defined perception of the cause exists, and that the patient is totally unconscious of that which distresses him; it is true also that the memory preserves no trace of these impressions. As we, then, to conclude with M. Moreau, of Tours, that "in reality there is no pain, because it is not perceived?" We freely admit that a certain modification of suffering takes place; but we think with MM. Blandin and Louget, that from the moment when an equivalent manifestation took place, the troicar communicated to the organic arrangement must have been the same as if the operation had been performed in the ordinary way. We must moreover observe, that those cases in which a total insensibility supervenes, are by far the most frequent, and that they occur, upon reconsideration of those cases where signs of suffering in different degrees have taken place, in the proportion of four to one.

In some instances, but very rarely, the sensibility, far from being blunted, has been refined to a very high degree by the ether. M. Vidal (de Cassis) has recorded three occurrences of this kind. The operations performed in these cases were on the generative organs. M. Ricord, who has operated under similar circumstances, met with the same results, and observes, that since the employment of ether they cry out a great deal more at the Hôpital du Midi. "Who knows," continues M. Vidal, "whether the ether, rendering insensible the greater part of the body, does not increase at the same time this vital property in some organs? Who can tell whether the generative sphere does not possess the faculty of withdrawing itself from the influence of ether?" It is our duty to observe that observations made in other hospitals do not in any degree approach to a support of this opinion.

We shall not quit the subject of sensation without referring to the strange and isolated action produced in certain cases more properly by ether. Some of those operated on have preserved their general sensibility, though unconscious of pain. They saw, they understood everything which passed around them, but manifested no appearance of suffering. One patient, operated on by M. Velpeau, for a tumour under the ear, "heard the crack-crack of the bistoury, but did not feel it." In short, the sensation of pain is not only in some cases extinguished or subdued, it undergoes a positive transformation and is changed into a sense of tickling, pressure, distention, &c.

(To be continued)

MIDDLESEX HOSPITAL.

CLINICAL NOTES.

By E. W. TUSON, F.R.S.,
surgeon to the Hospital.

CASE I.—Strangulated inguinal hernia. Operation; inflammation; abscess; cure.

William Potter, aged forty-four, was admitted into the Middlesex Hospital on the 18th of March, under Mr. Tuson's care, with strangulated inguinal hernia. He stated that he had been ruptured for the last twenty years, that it came on whilst he was at work as a stable-man; but he did not wear a truss for twelve years afterwards, at which time he changed his employment, and became the driver of a coach, which calling he had followed ever since. About seven or eight years previously he found he could not return the swelling, and went to a surgeon, who reduced it, and adjusted a truss, which he had worn up to the time of the hernia becoming strangulated. In the night of the 15th of March, the patient had a violent cough, when he found the hernia down, and he could not return it. He sent for a surgeon, who employed the taxis without success, and, at the expiration of three days, he was brought to the hospital. When examined, a soft and moderate-sized inguinal hernia was discovered on the right side, which, from its being so soft, induced Mr. Tuson to believe it might be easily reduced, but he was unsuccessful in the application of the taxis. Having observed the beneficial effect of ether in producing muscular relaxation, he considered this a case that would at once yield to its influence, and consequently ether was employed. The patient was fairly under its effect, when the taxis was again resorted to, and continued for at least twenty minutes, but without producing the least satisfactory result. A consultation was, therefore, called, when it was determined that the operation should be performed without delay. Nothing particularly unfavourable presented itself during the several stages of the operation; the intestine was readily returned, and also a portion of omentum, after the division of the stricture. The edges of the wound were brought together by sutures, a compress and spica bandage applied. The patient was removed to the ward, and went on favourably for the two following days; had an alvine evacuation without an aperient.

March 21. The symptoms were all favourable, except that the patient was restless and wished to go home, saying he should have every care and attention at home; but in the afternoon his wife came to see him, when she informed the house-surgeon that she had no means of giving him any assistance or care at home, and begged that he might remain at the hospital. Soon after she had left he became more excited, persisting that he would leave; he then became delirious, so much so that it was necessary to remove him from the ward to a separate room, and use restraints. The apothecary was now requested to see him, who was induced to believe the attack delirium tremens; he ordered ten grains of calomel and three grains of opium to be given immediately, and repeated if necessary.

22. Had passed a restless night, little or no sleep, but he was more quiet and composed; the wound was dressed, it was much swollen and inflamed. The scrotum and penis were also much increased in size. The ligatures uniting the wound were removed. Pulse 100; tongue much furred; skin natural. A pint of porter was ordered. Solution of acetate of ammonia half an ounce; decoction of bark one ounce three times a day.

23. Had passed a better night; had some cold chills last evening; pulse 96; tongue furred.

* "Mr. Tuson sends with the above the following note:—"I shall feel obliged by the insertion of the two following cases in an early number of your valuable journal, as I consider them interesting and instructive; they illustrate the influence of ether under different circumstances."

Bowels had acted twice. The scrotum and penis were more swollen and inflamed. There was a circumscribed swelling in the original seat of the hernia, which proved to be an abscess; some healthy pus made its escape when the scrotum was pressed. Poppy fomentation, with extract of hemlock to be applied over the swollen parts, and a small poultice over the abscess. The bandage was not again applied. To take decoction of bark two ounces, tincture of bark one drachm, three times a day; four ounces of wine, two pints of porter, one pint of strong beef-tea each day.

26. Had been progressing favourably. The abscess had discharged freely, and the swelling had diminished. At the lower part of the prepuce there was an irregular ulcerative surface which caused him some considerable pain.

27. Better in every respect; the abscess discharged freely, and the parts were less swollen. From this period he gradually improved, the abscess healed kindly, and after it had done so a small collection of pus discharged itself at the lower part of the scrotum, which afterwards healed, and also the ulcerated surface on the prepuce. He took three grains of disulphate of quinine every four hours; two pints of porter, twelve ounces of wine, two mutton chops, and two eggs, every day. He had been very low, but now began to rally, and went on improving until he was discharged from the hospital on the 16th of April, perfectly cured, and it was not necessary for him to wear a truss.

CASE II.—Compound comminuted fracture of the tibia and fibula, extending into the ankle-joint. Amputation; sloughing of the stump; cure.

Robert Hugkustone, aged thirty-four, porter, admitted into the Middlesex Hospital on the morning of the 19th of March, under the care of Mr. Tuson, with compound comminuted fracture of the right leg. About half an hour before his admission, while cleaning a lamp, ten or twelve feet from the ground, the ladder slipped from under him, he fell; and a pail of water which hung on the ladder above him fell on his leg, causing the accident. The upper portion of the tibia was seen protruding through a hole in the stocking to the extent of two inches. Upon examination the fracture was found to be between three and four inches above the ankle, the lower end of the tibia being split down completely into the ankle-joint. A consultation was called, and it was deemed advisable to have recourse to immediate amputation, which was performed under the inhalation of ether.

In a few minutes the patient was perfectly under its influence, and the operation was commenced without any evidence of pain; the nouthpiece was then withdrawn, when, in consequence of the apparatus having been previously racked, a portion of it fell in pieces and was rendered perfectly useless. The patient, before he completed the dressing of the stump, becoming conscious for want of another inhaler, a saturated sponge was held before his mouth and nose, and after a few inspirations he was again perfectly under its influence. After the patient had been removed to the ward, he expressed his best thanks for the little pain he had felt during his operation. Upon dressing the stump for the first time on the 23rd, there was considerable discharge, which had an unhealthy appearance; sloughing then commenced and extended for some few days, until the whole of the under flap gradually sloughed away, as well as the integumentary covering on the upper surface of the limb to the extent of three inches above the end of the bone, exposing a portion of the tibia, which is dead and will exfoliate. With the exception of the exposed bone, the whole of the stump at the present time (April 20) appears healthy, and is granulating nicely. Although there has been profuse discharge the whole time, his general health does not appear to have suffered; he has been allowed daily since the commencement of the slough (March 24), up to the present period (May 8), porter one pint, wine twelve ounces, a mutton chop, a pint of strong beef-tea, and two eggs, and has been taking,

three times a day, three grains of disulphate of quinine, and an anodyne at night.

Under this treatment the stump has been gradually improving and is considerably healed, although the dead portion of bone has not yet come away. The patient sits up each day, moves about the ward with crutches, and is in every respect rapidly recovering.

74, Harley-street, Cavendish-square, May 8.

OF THE PREPARATION OF GLUTEN BREAD, AND OF THE ADVANTAGES WHICH IT PRESENTS IN THE TREATMENT OF DIABETES, AND OF SOME OTHER AFFECTIONS.

By M. BOURCHARDAT.

Translated for the MEDICAL TIMES by ALFRED MARK-
HAM, Esq., Surgeon to the Western German Dispensary, and formerly Externe to the Venereal Hospital, Paris, &c.

All works on chemistry contain a description of the process commonly employed for procuring gluten; but, as it cannot be had recourse to with economy for the object we have in view, I will describe that discovered by M. E. Martin, and of which an account is given in M. Dumas' work.

The new process of M. E. Martin, of Vervins, consists in forming a paste or dough of the substance from which the gluten is to be extracted, and then submitting this paste to a continued washing on a metallic sieve, No. 120. We thus obtain, in the liquid, the starch in suspension and the soluble matter; and in the sieve the gluten unaltered, provided we operate on wheaten flour of good quality.

The paste is formed in the same manner as in the making of bread, with this exception, that it is kept rather more firm. About 40 parts of water to 100 of flour are employed, and the paste is allowed to stand during half an hour in summer and an hour or two in winter, before washing it, in order that the gluten may be well hydrated.

Dough, made with the very best flour, may be washed in the summer time twenty minutes after it is formed; coarser flour requires a longer time, which may vary from two to six hours.

The dough is washed over a tub, conveniently arranged and proportioned in size to the number of washings that we wish to employ. On it is placed a metallic sieve, No. 120, lined, for the sake of greater solidity, with a plate of sheet iron, No. 15, having a border round it measuring about twenty centimetres. A tube perforated with holes, placed above the sieve, injects over nearly its whole surface numerous very fine streams of water, the flow being regulated at pleasure by means of a stopcock. In commencing the operation, the tub is filled with clear water, as fresh as possible in summer; the washer then takes a piece of dough, weighing about five kilogrammes, and holds it under the tube; he afterwards places it on the sieve, and kneads it with both his hands, at first gently, and subsequently, as the gluten forms into filaments, with greater force, until the water no longer passes through white.

The fresh gluten, obtained by washing the dough, forms generally rather more than a fourth part of the flour employed. This proportion, however, varies according to the nature of the corn: in that from the south of France it is somewhat greater, while in that from Sicily and Barbary it is often as much as one-third.

This gluten requires to be cleansed by washing from a little bran and some impurities. Having thus obtained the gluten, the following precautions require to be observed in converting it into bread. It is important to use it as fresh as possible, for when it has been prepared for several hours it begins to be impaired, and does not form well into bread. First, then, it is drained, and afterwards mixed, by long and repeated kneading, with one-fifth of flour of first-rate quality, a sufficient quantity of salt, and a little yeast. It is then allowed to ferment, and, when it has well risen, placed in a moderately hot

oven, where it is left a sufficient time to drive off as much as possible of the moisture. We thus obtain a very light and rather elastic kind of bread, of a tolerably agreeable taste and smell, and which more resembles cracknels than any other kind of food.

To the dough of this bread, butter, eggs, cream, cheese, &c., may be added, to suit the taste of the patients.

We will now examine the properties of gluten bread, and in doing so we will begin by quoting the passage from the report of the commission on gelatine which relates to gluten.

"*Experiment on the Nutritive Properties of Gluten.*—After these very incomplete trials of the nutritive properties of the immediate principles taken from animals, we wished to examine those of the same principles taken from vegetables, and particularly the alimentary qualities of gluten and fecula.

"Gluten, separated either from wheaten flour or from that of Indian corn, presented to us a phenomenon we did not observe when experimenting with the immediate organic principles, which all occasion, more or less, repugnance in animals obliged to feed upon, or even to eat, them.

"The gluten, notwithstanding it had a faint and somewhat sickly smell, and nothing agreeable in its taste, was taken without difficulty from the very first day, and the animals continued to make use of it uninterruptedly for three months, without any disgust. The dose was from 120 to 150 grammes per day, and the animals preserved all the appearance of excellent health. This fact was the more striking from its being in opposition to the rule which appears to result from the very numerous facts previously mentioned, namely—that an alimentary substance, especially if it is an isolated immediate principle, is not capable of supporting life beyond a time which is never very long.

"Here, on the contrary, is a substance, formerly considered as an azotized immediate principle, which, without either preparation or condiment, excites neither repugnance nor disgust, and which, uncombined, affords nourishment for a long time.

"Dr. Prout, a celebrated English chemist, resting on the well-established fact, that milk is sufficient of itself to constitute an excellent nutriment, has taken its composition for a type, and has reduced the general composition of the food of animals to the following form:—

1. An azotized matter, casein.
2. A fatty matter, butter.
3. A non-azotized matter, neutral-sugar of milk.

1. Various alkaline and earthy salts.

"Still gluten itself affords nourishment, although more simple in its constitution than milk, or the aliments that are calculated from its composition."

Gluten bread is chiefly employed in cases of diabetes.

In conclusion, I may state that I consider gluten bread a very nourishing aliment, well adapted for persons debilitated either by age, by privation, or by long illness. Moreover, I consider it extremely useful for patients labouring under that affection of the stomach called dyspepsia, or gastralgia, in which saccharine, and sometimes even feculent, matters become rapidly acidified in the stomach, and which, in consequence of this exaggerated physiological result, cause pain often of a very acute character, and hinder the process of digestion.

CASE OF OSSIFICATION AND DILATATION OF THE ASCENDING AORTA—HYPERTROPHY AND DILATATION OF THE HEART—HYDROPERICARDIUM.

By H. EVANS, Esq., Pwllheli, North Wales.

HISTORY.—A married woman, aged thirty-five, the mother of several children, complained of pain in the right hypochondriac and umbilical regions, soon after her confinement. Upon ex-

amining the seat of pain, a large prominent tumour was detected, and supposed at the time to be scirrhus growths connected with the right lobe of the liver. The tumour presented no irregularities, but was very tender when touched; her complexion was sallow, and she complained of general weakness. She was lost sight of for six months, when she had, in addition, ascites, and anasarca of the lower extremities, the latter having had the priority; she had had hæmoptysis, and was then much harassed with a tearing cough. Upon auscultating the heart, an unusually loud bruit was audible along the sternum in front of the course of both carotids, and equally distinct on both sides; also behind, throughout the whole extent of the cervical region. Both sides, in front, sounded dull to percussion, the healthy breathing being limited to the upper regions, as she lay upon her back. Behind, there was bronchophony and gurgling over the left scapula, and over the right, small and large crepitation; she had then profuse hæmoptysis, which continued until her death, three days afterwards.

REMARKS.—In this instance a great error was committed in the diagnosis, owing, I may say, to the very unconnected account of the commencement and progress of her complaint; and for this reason only has it any claims for consideration, if any at all; fortunately, however, both for patient and surgeon, it was a case where medicine could have done but little, and art still less, for the patient's relief or cure. Upon inspection after death, the pericardium was found distended with clear serum; the aorta much dilated and extensively ossified, all its cavities much enlarged, the organ itself being three times the size of her fist; all the valves were entire but the aorta, these were prevented from performing their functions on account of the increased calibre of the artery; and their insufficiency as floodgates was very palpably seen by the fruitless attempts to fill the aorta with water. There had been no effusion into the pleura, as was surmised, but both lungs, especially the left, were so much encroached upon by the heart as to present, when sliced, a uniform pitch-like blackness, portions of them when put into water hardly floating; there were no traces of tubercles; the increased density of the lungs, together with the very profuse sanguineous effusion into the bronchial cells and tubes, being sufficient to produce the physical signs described. The liver was healthy, but much displaced during life by the diaphragm and heart; I say during life, for prior to the examination, in fact a few hours after death, the tumour could not be found, owing to the collapsed and rigid state of the diaphragm and adjacent parts.

FUNGOID DISEASE OF THE TESTICLE.

John Reay, aged two years and a half, was brought to me the beginning of December, 1846, with very considerable enlargement of the scrotum. I learned that it was first noticed eighteen months back, and that several physicians and surgeons had been consulted, who had prescribed various remedies without in any way staying the progress of the disease. Upon examination I found the right testicle nearly the size of a cricket-ball, of bony hardness, except one spot, which was soft, and the scrotum covering it thin; the child's health was suffering from hectic, and not doubting the nature of the disease, advised amputation as the only means likely to be of use; this was consented to, but the mother, who was near her confinement, wished it to be deferred until she was in a state to render the attention that would be required; shortly afterwards the skin gave way and hæmorrhage of a considerable amount followed. Three days from this, I was about to examine the parts, when a second bleeding took place, and I had difficulty in staying it; the blood came *per saltum* and of a florid red; it was without doubt arterial: the child's countenance was ghastly, and I deemed

delay would prove fatal; therefore, assisted by Mr. Green, I removed the diseased testicle, which weighed over twelve ounces; the greater part of the scrotum was firmly adherent to the gland, which rendered the operation both painful and tedious. The wound healed within a fortnight, and the child's health has much improved. Cambridge, Feb. 15. R. Southess.

CASE OF SEVERE WOUND OF THE PUDENDUM DURING PREGNANCY, ATTENDED BY ALARMING HEMORRHAGE, WITH OBSERVATIONS.

By ALFRED H. MINTOCK, M.D.,

Fellow and Licentiate of the Royal College of Surgeons in Ireland; Ex-Assistant of the Dublin Lying-in-Hospital; Vice-President of the Dublin Obstetrical Society; Lecturer on Midwifery, &c., in the School of Medicine, Park-street, &c. &c.
(Communicated to the Dublin Obstetrical Society.)

The following case, which I saw in conjunction with my esteemed friend Dr. Brunker, surgeon to the Louth County Hospital, though possessing no claims to novelty, is nevertheless, I think, interesting and instructive. It is not of importance in any other particular, it at least shows what an amount of shock and bodily injury may be sometimes sustained during pregnancy, with impunity to the process of gestation, and without any bad effect on the delicately-organized embryo. The subject of this case was a poor woman of healthy constitution, aged forty, and who at the time of the accident (April 23, 1817) was in the fifth month of her fifth pregnancy. It appeared, so far as we could elicit, that she fell from the eighth or tenth step of a ladder, which she was in the act of ascending, and in the fall the parts of generation forcibly struck against the edge of an open barrel, or water-cask. Immediately upon the receipt of the injury a profuse discharge of blood began to flow from the vagina, inasmuch that when we saw her, about twenty minutes after, it was quite manifest she had sustained the loss of an enormous quantity of blood. Her lips and countenance were perfectly pallid and bloodless, and the pulse at the wrist so weak as to be scarcely perceptible. The bed on which she lay, as well as the floor of the room, gave strong evidence that the loss of blood must have been very considerable. On examination we found the entire of the left labium, and adjoining portions of the thigh and buttock, to be the seat of extensive swelling and ecchymosis; and the skin in parts was abraded. The vagina was occupied by a large clot, and when this was removed we ascertained that the meatus urinarius and anterior part of the vaginal orifice were a good deal cut and lacerated, so that in one situation the angle of the pubis was almost denuded to the perineum. It was evident that this wound had been the source of the hemorrhage (which was not now going on), as there was none other from which it could have come, and the os uteri was perfectly closed, high up, and possessing the characters natural to it at this period of pregnancy. The catheter was with some difficulty introduced into the canal of the urethra; but, this done, it passed on readily without further interruption into the bladder. About half a pound of clear urine was evacuated. Before withdrawing the catheter we carefully examined the tract of the urethra with the finger, and in this way fully satisfied ourselves that, except at the meatus, its integrity was unimpaired. Having thus ascertained the nature and extent of the injury, we proceeded to put in practice the plan of treatment that seemed most advisable under all the circumstances of the case.

As no hemorrhage to any amount was at this moment going forward, some wine was first administered to her, and, so soon as the pulse indicated a return of strength, we introduced a large soft sponge completely into the vagina (which was unusually relaxed); this was accomplished without occasioning any great pain or annoyance. A second sponge was next placed within the vulva, so as to partially occupy the vaginal

orifice—the remainder lying between the labia. This done, a T bandage was tightly applied, by means of which the sponges were effectually secured in their proper places. As soon as she was comfortably settled in bed a full opiate was given to her. On the following morning (the 1st instant) we found her greatly improved in every respect. The pulse, though weak, was steady and regular; she had taken some nourishment, and had felt no inconvenience from the vaginal plug, neither had there been any recurrence of hemorrhage. It was necessary, however, to draw off the urine with the catheter, which operation had to be repeated in the evening. Though the bowels had not been moved for two days, we thought it more prudent to abstain from giving any purgative medicine; nor did we meddle with the plug, but just left it as it was. At morning visit next day (5th inst.), she seemed to be going on favourably in every respect, but was complaining much of headache and weakness. She said she had felt the child moving frequently during the night, and as vigorously as before the accident. She did not express the least pain or distress from the presence of the sponges in the vagina; nevertheless, as it was now forty hours since their introduction, we removed them, and syringed the vagina with tepid water. There was no discharge of blood whatever from the wound, which seemed disposed to suppurate slightly; and the conused parts presented merely a swelled and ecchymosed appearance, such as might have been expected. During the week following there was a good deal of purulent discharge from the vagina, but this gradually disappeared. Within a fortnight from the date of the accident she was able to be up and walking about, and only suffered from the weakness and other constitutional effects produced by the enormous loss of blood she had sustained. I may just mention that, for several nights successively, she could not sleep without the assistance of a morphia draught; but after she got up this was no longer required.

It may perhaps be thought scarcely necessary to make any comments upon this case, whose history I have thus briefly detailed; nevertheless I would beg leave to offer a very few remarks. I conceive that the authentic history of every case of a grave nature, such as the foregoing, will furnish illustration of at least one or more points of practical importance, and on this account will possess some degree of interest, though in other respects it may be dry and unprofitable. In the instance before us the leading points deserving of attention are, I think, the following:—

1. The profuse loss of blood which took place from the wound of the vulva, even though it was by no means extensive, or of that particular kind which, by experience we know, is apt to bleed freely. This strikingly exemplifies a fact of considerable practical importance, and one not sufficiently recognised, namely, that the state of pregnancy has a marked effect in rendering the amount of hemorrhage from any wound of the generative apparatus more inordinate than it would be under opposite circumstances. This may, I think, be satisfactorily accounted for by the change which takes place in the vascular condition of these parts after the uterus has become gravid. In the first place we find that an increased quantity of blood is determined to the genital organs during gestation; and, secondly, that the return of this blood is very much impeded in consequence of the pressure exerted by the uterus upon the venous trunks emerging from the pelvic brim.

In the second place, the favourable termination of this case holds out much encouragement to pursue the same plan of treatment under circumstances of a similar nature. I once saw a case where life was endangered from hemorrhage consequent on the tear of a large cicatrix in the vagina. It took place after the expulsion of the head, during labour, and the laceration extensively involved the recto-vaginal septum. Here it was necessary to tightly plug the vagina, and

to compress the bleeding surfaces against the sacrum, in order to control the immediate effusion of blood. To this measure there was the less objection as the uterus was well contracted.

Lastly, the case I have narrated shows us in a very striking manner what an amount of resistance is occasionally opposed by the constitution to the operation of causes whose tendency is to interfere with the process of utero-gestation.

I should not omit to mention that, at my desire, this woman was carefully examined with the stethoscope on the 27th instant (that is, exactly three weeks and three days after the accident), and the fetal heart's pulsations were then strong and vigorous.

2, Gardiner's-place, Dublin.

ANEURISM OF THE ASCENDING AORTA.

By WILLIAM THOMPSON, Esq., Surgeon, Newark.

Daniel Lunn, aged thirty-five, bricklayer, of lymphatic temperament, returned from his work between six and seven o'clock on the evening of the 1st of April. Sitting down in his house he complained of vertigo, fell back and became senseless. Mr. Dobbs, the medical attendant of the Odd Fellows' Club, to which he belonged, was sent for; in a short time his assistant came, and, finding him pulseless, applied what restorative measures were at hand, and the patient was carried up stairs to bed. Although he became restored to consciousness, yet the pulse could not be felt at the wrist; his countenance was pallid; lips and tongue of a livid colour. Mr. Dobbs saw him soon afterwards, exhibited *sp. ammon. a. in camph. julep.* every half hour, and ordered brandy.

Afterwards I was sent for on account of my attending his wife in her confinement. To appease her anxiety I sent my assistant, who found him with a livid countenance, cold hands and feet, and no perceptible pulse at the wrist. He gave a mustard emetic that caused him to vomit some undigested food, and then applied mustard cataplasms to his feet. No symptoms of reaction appearing, he gave *3 iij. of sp. ammon. a. in toast and water*, which had a most beneficial effect; the pulse revived and gradually increased in vigour, and general warmth pervaded the system, the countenance and tongue becoming more natural.

I had no more of the patient until one o'clock the next day, when his wife came to me, saying he was as bad as before; that his pulse could not be felt, and that Mr. Dobbs had seen him twice that morning, and she was afraid he would die. At her request I visited him immediately; not a pulsation could be felt in the wrist, neither could I distinguish it over the region of the heart. The patient was collected in his mind, and replied to the questions put with little apparent anxiety, although distress was depicted in his features. His lips were livid, the tongue congested, and the finger-nails dark. I gave him *ext. capsici. gr. v. in pill*, which he got down with some difficulty mixed in soft bread, and drank after it *3 j. sp. ammon. a. in tepid water*; the pulse in a few minutes beat tremulously at the wrist. In half an hour repeated *gtt. xl. of ammon. a. with a table-spoonful of brandy in water*, which was ejected immediately; it, however, tended to establish and strengthen his pulse, which became more regular, and he felt better. I desired the attendant to give him strong beef-tea, also gruel strongly seasoned with ginger, and keep him quiet. In an hour's time he took one of the following powders:—

R. Hydr. c. creta pulv. opii. a. gr. j. pulv. cinnam. c. gr. iij.; ft. pulv. 6ta hora sumend.

R. Sp. terebinth. 3j; ol. lini, 3j.; ft. linim. applicand. abdomini ter in die.

In company with Mr. Dobbs I visited him on Saturday the 3rd, at ten o'clock. We found our patient with a tranquil, natural countenance; tongue white and furred; pulse 80, weak and irritable, but compressible; the abdomen rather

swollen and tender between umbilicus and epigastrium.

R. Ol. right, 3 j statim, as the bowels had not been moved since the first night. Ropete pulv. 6ss horæ.

4th. The bowels had been well opened five or six times the previous day; had passed a comfortable night; pulse soft and natural; the tongue covered with brown fur in centre, and red at the edge; his urine plentiful, with a flocculent red sediment. Mr. Dobbs and I considered he laboured now under slight dyspeptic symptoms, by having tenderness on pressure at the epigastrium.

R. Liq. potass., 3 ij.; Tr. hyoscyam., 3 iss.; inf. gent., 3 vss. m. ft. mist. cap. coch. ij. mug. ter in die.

R. Hydr. c. creta, gr. ij; ext. hyoscyam., pil. aloes c. myrrh. a. gr. iv. m. ft. pil. ij. omni nocte cap. Allowed coffee and toast, rabbit and broth, with gruel *ad libit*.

On the 6th, Monday, he dressed and went down stairs for an hour. On the 6th, at a quarter to nine A.M., he suddenly died.

I considered this case exhibited symptoms before death of pulmonary apoplexy.

Post-mortem Examination 26 hours after Death.

—The abdominal viscera were healthy, except an enlargement of both lobes of the liver: being incised, they displayed congestion and patulous distention of the biliary veins. On removing the sternum, the lungs were loose, except in the right side of the chest, where old adhesions were found at the upper part; half a pint of bloody serum was collected in each cavity of the pleura, and the lungs were much congested at their bases: being cut into, inflammatory action had been going forward from the obstruction during the few last days of his existence. The pericardium was much distended, and, on opening it, was full of coagulated blood; this was discovered to have escaped from the rupture of an aneurism of the ascending aorta, half an inch external to the semilunar valves, this opening being sufficiently large to admit the point of the little finger. Upon laying open the aorta into the heart, the vessel was in an unhealthy state from deposits within the lining membrane in small pesty patches; the semilunar valves more vascular than is usual. The size and substance of the heart were natural, only more blanched than usual.

MIDWIFERY.—BIRTH OF THE CHILD WITHOUT THE KNOWLEDGE OF THE MOTHER.

Communicated by H. G. KING, M.B.C.S., L.A.S.

Through a professional experience of more than twenty years, attended with almost every variety of circumstance, I remember nothing in my readings or practice that might offer as a parallel to the following cases. I shall abstain from making any comments more than necessary to their elucidation, leaving my readers to supply whatever importance they may think them worthy of. It has been denied that it is possible for the parturient mother to give birth to her offspring unconscious of the fact, unless in a state of coma: by this I mean that state of compression of the brain arising from physical causes. This I conceive to be a state of torpor consequent upon over-mental excitement.

B. T., aged thirty-six years, fair complexion, spare habit; light eyes, somewhat receding in their orbits; nervous temperament, lax muscular structure; the mother of nine children, six of whom are living; had barely reached the seventh month of gestation, when I was requested to pay her an immediate visit. I found her suffering under hysterical paroxysm, occasioned by seeing her husband in liquor—an unusual circumstance. After ordering her to bed, with strict injunctions that she should be kept quiet, I gave her a sedative draught and left her in the care of her nurse, not doubting that the excitement would wear off when the family alarm had somewhat subsided. About four o'clock the following morning I was again summoned to this

patient, whose paroxysm had increased. She presented the following appearance: she was lying on her back; there was a tremulous motion of the eyelids, her features otherwise calm and placid; her breathing natural; pulse 90; head cool; cold water dropped upon the face produced no change in expression. I was much astonished on my arrival that a living child had been born, and the placenta had passed; there was no hemorrhage, nor anything but what is common in natural labours. Fluids were swallowed with great difficulty; bottles of hot water, sinapisms, stimulants, &c., were tried without effect. I resolved to watch the case, to see her nature properly sustained, and to await the issue. A period of ten or twelve hours elapsed before any sign of sensibility, and this was manifested, after calling to the patient, by a partial cessation of the tremulous motion of the eyelids and effort made to respond to her name. This dawn of returning reason was not fully established for thirty hours after the attack. I should have observed, that in no instance could the state of the pupil be satisfactorily obtained. Both mother and child did well, and are living now, she having no recollection of the birth nor of any matters connected with the event, nor did she manifest any uneasiness or sign of pain during the expulsion of the child and placenta.

The second case was a female of about twenty-eight years of age, the mother of two children, both living; this was consequently the third accouchement, nothing particular occurring in the former labours. I was hastily summoned to this lady, who had expressed great uneasiness lest I should not be in time. On entering the room, I proceeded to the bedside to assure my patient I was at her service; she spoke and acknowledged the attention, and shortly relapsed into a state which appeared like sullenness; she was lying on the left side, but in a position I wished to improve, and to my repeated directions so to do she paid not the slightest attention. The uterine action continuing for about twenty minutes, a healthy infant was born, and shortly after the placenta came away. This event had scarcely happened, when my patient, looking up, expressed her astonishment at hearing the infant cry; she could hardly be persuaded that it was born, assuring me that she had no knowledge of the event. I had noticed her head huddled in the bedclothes, and supposed it intended to stifle any manifestation of pain; she became perfectly conscious, had no interruption to her recovery, and still declares that the birth of this child is a blank in her memory, and was quite unknown to her.

In neither of these cases is there any object in concealing the truth, both women being married and fond mothers, and had anticipated the event. In the first case the appearance of the patient left no doubt of her assertion; the second was a more transient suspension of the mental influence; but the same assurance is given by both. I was unable to account for the loss of sensorial power here, but after some months epilepsy supervened, and revealed the mystery.

ON OVARIAN DROPSY.

By J. B. BROWN, Esq.,

Consulting Surgeon to the Paddington Lying-in Charity.

In the report of the meeting of the Medico-Chirurgical Society, held March 23, where a paper was read from Mr. H. E. Burd, "On the Successful Removal of an Ovarian Tumour complicated with Pregnancy," I find some remarks respecting my plan of treatment which demand comment. In the observations made by Dr. Locock, after stating "that he had seen several cases in which pressure had been tried with the most favourable results," he goes on to say, "He thought that the cases treated by Mr. Brown deserved the attention of the profession, though he thought that Mr. Brown was wrong in giving mercury and diuretics, for they were not only useless, but did positive harm. In his (Dr. Locock's) cases,

Mr. Brown's plan was followed, but no mercury was given, and they went on well." I am glad to have this opportunity of stating that these remarks very much coincide with my present opinion, and I have for some time discontinued the use of mercury in treating patients for ovarian dropsy; and in the last case to which I was called by Dr. Locock, and which he alludes to on the above occasion in the following words, "Four months since, another case had occurred to him: the cyst was simple, the health good, eleven pints of fluid were drawn from the tumour, and firm pressure was applied, and had been kept up to the present time." I did not use mercury in any form. I intend, very shortly, publishing more fully my reasons for altering the plan of treatment in this respect, and illustrating such reasons by unsuccessful cases. This leads me to the remarks made by Mr. Caesar Hawkins at the same meeting:—"He had put a question to Dr. Locock respecting a patient of his, because he had doubts regarding the success of Mr. Brown's treatment. Thus two of the cases returned as cured Mr. Lee had discovered were dead, a third had died from suppuration in the sac, and he (Mr. Hawkins) had heard of a fourth case which was fatal." When I read this, knowing that not one of the cases I had published as successful had since died, I waited on Mr. C. Hawkins for an explanation, and he very politely referred me to Mr. Thomas Safford Lee's book, page 161, where I find the following words:—

"This plan of treatment has been given to the profession, and apparently sanctioned by a number of successful cases; but I am bound to add that some of those cases, called and published as successful, have come into other hands; and I am authorized, by a physician to state that two of Mr. Brown's cases have come under his charge: one died of ovarian dropsy, and, on a post-mortem examination, the cyst was found still to exist as large as before; the other is still ill—the cyst has refilled, and this gentleman has been obliged to have recourse to tapping. This fact reduces considerably the value of Mr. Brown's cases." After reading these remarks, which, although much modified from Mr. C. Hawkins's statement, were equally unfounded as far as regards any cases published by me, I also waited on Mr. Lee, who said that he was authorized by Dr. F. Bird to make the remarks he had made in his book. I then called on Dr. F. Bird, who assured me there was some mistake in the report of his observations as made by Mr. Lee, for that he did not say "any cases I had published as successful had since died," but that "several cases had come under his notice, after being treated by me, one or two of which had died in his hands, as he (Dr. F. Bird) believed from the effects of my treatment. I subsequently received the following note from Mr. Lee:—"I have communicated with Dr. F. Bird on the subject of your letter to me; who, at my request, has again read the passage of my work to which you refer, and he agrees with me in thinking that the word "published" does not necessarily apply to the observations contained in the lines 28 and 33, page 161; and Dr. F. Bird wishes me to allude to this point as explanatory of the want of correctness, he at first thought, I had permitted to escape me. Perhaps you will again peruse the passage referred to, and, if you are not fully satisfied, I will willingly publish a much more full explanation than may even seem necessary."

It will thus be seen that the whole statement which emanated from Mr. Caesar Hawkins was founded in error, and, although unintentional on his part, is calculated very materially to damage the mode of treatment I advocate.

I take this opportunity of stating that the last case (that of Mrs. D.), which I published as successful in the *Medical Times*, has not proved so: the fluid returned, and a most malignant scirrhus disease of the uterus has developed itself, which renders it most improbable that she will live much longer.

In 1845 I published the case of Miss E. as successful, wherein it will be remembered there

were three cysts, and each cyst contained different-coloured fluids; this lady married a year afterwards, and became pregnant, and at the full time I delivered her of a healthy child, and then discovered that a fresh dropsy had returned, probably from the formation of a new cyst, because the fluid drawn off was of a different character from that drawn from either of the former ones. My plan of pro-seure was steadily persevered in, and no mercury was given. She has since continued to suckle her child, and when I last saw them, seven months after her confinement, both mother and child were well, and no appearance of a return of fluid was perceptible.

In concluding these hasty remarks I would wish to observe that all the other cases I have published as successful are still well, and not one has had any return of fluid in the cyst.

27, Oxford-square, Hyde-park.

PROGRESS OF MEDICAL SCIENCE.

France.

ACADEMY OF MEDICINE.

Meeting of May 4; M. BÉGIN in the Chair.

M. Bichetenu read a report on a paper by M. Colles, on the pathogenic history of chronic diseases. The author of the essay was of opinion that all chronic disorders had one origin, and when properly combated might in every instance be arrested. The reporter could not agree with the essayist in his general views, which, however, he considered to be ingenious. The report, after a short and uninteresting debate, was adopted.

GENERAL PARALYSIS OF THE INSANE.

In a former communication we reported two cases of general paralysis, forwarded to the academy, with the *post-mortem* examination, by Dr. Belhomme. M. Rochoux reported on these two cases, and the conclusions which were drawn therefrom by Dr. Belhomme. In all similar cases, the author referred the general paralysis to some anatomical change in the cerebral organs.

M. Prus remarked that the paralytic symptoms observed in the insane presented much interest in a pathological point of view, and constituted a question well deserving of the attention of the academy. Esquirol, whose ideas on the subject were in their fullest extent adopted by M. Calmeil, conceived that, although the paralysis was often accompanied with anatomical alterations of the cerebrum, still these were so variable and so numerous that the loss of voluntary power could not be connected with propriety with any one peculiar morbid change. In general, paralysis was looked upon as being constantly the result of a congestive state of the encephalon; this notion was undoubtedly erroneous, and M. Prus was certain that he had recently read the account of a case of paralysis which had been treated by antiphlogistic measures, whilst an opposite line of treatment was indicated, and might possibly have saved the patient.

M. Bouilland was of opinion that the employment of the word-paralysis in the cases of insanity alluded to was an abuse, or rather an error, of language. These patients were not in reality paralyzed; no hemiplegia was present. They might, to a certain extent, be compared to those animals whose cerebellum had been more or less injured during physiological experiments.

M. Rochoux, in reply, said that he thought the denomination of general paralysis was perfectly applicable to the cases in question. Loss of power over the voluntary muscles was undoubtedly observed, and in all the cases in which a careful *post-mortem* examination of the brain had been made, alterations had been detected which accounted fully for the symptoms noticed during life.

The report was adopted.

The meeting adjourned at five o'clock.

SOCIETY OF SURGERY.

Meeting of April 21; M. LENOIR in the Chair.

UTERINE HÆMORRHAGE DURING PARTURITION.

—Dr. Senn (of Geneva) remarked that one of the most anxious moments for the practitioner in a case of midwifery was that which follows expulsion of the fetus—a moment frequently rendered perilous by sudden and abundant flooding. To obviate this accident, Dr. Senn proposed three measures which, although extremely simple, he thought worthy of the attention of the society. The first consisted, immediately after the birth of the child, in seizing the umbilical cord at two inches from its attachment to the belly, and forcing back by repeated pressure the blood into the placenta; the cord should then be tied and divided below the ligature, and no blood would be discharged. The second measure recommended by Dr. Senn consisted in gentle pressure on the abdomen, with a bandage. This plan rendered delivery much more prompt than usual, and it was, besides, assisted by the circumstance that the placenta, distended by the blood forced back into it by previous pressure of the cord, could not follow the retraction of the womb, and was consequently detached speedily and expelled into the vagina. Thirdly, M. Senn considered it extremely important to maintain the perfect immobility of the mother, during two or three hours after delivery, the slightest motion even of the head being in some instances sufficient to cause the separation of a protecting coagulum, and the recurrence of flooding.

LACERATION OF THE LUNG WITHOUT FRACTURE OF THE RIBS, BY DR. GOSSELIN.

This paper was divided into three parts. In the first, the author recorded two cases in which, after an external injury, the lung had been lacerated, without any appreciable fracture of the neighbouring ribs. The damage sustained by the lung was proved in the first case by the stethoscopic signs of a cavity containing a fluid; in the second, by hydro-pneumothorax; and in both by a sanguineous expectoration, which lasted several days. The second section of the paper was consecrated to historical researches on the subject, and the third to a description of the symptoms and to the appreciation of the mechanism by which the pulmonary laceration was produced, and which Dr. Gosselin conceived to be the closure of the glottis at the instant of the accident.

M. Malgaigne observed that the same accident was observed in other cavities—the abdomen, for instance—when, without any appreciable injury of the parietes, the intestine was sometimes lacerated. In such cases science was totally unable to explain the fact, and he was not satisfied that M. Gosselin's theory of the occurrence, as far as regarded the chest, was correct. With regard to the diagnosis, it was sometimes impossible to detect the existence of fracture of the ribs; and in M. Gosselin's cases, fracture might have existed, and caused all the internal mischief, without being recognised. As to the treatment, M. Malgaigne thought that a tight bandage round the chest was the application from which the patients derived the greatest relief.

M. Robert said that it was difficult to admit in M. Gosselin's first case the existence of a laceration of the lung, pneumothorax not having been observed. How could the lungs be torn without effusion of air taking place into the pleura? M. Robert could not agree in recommending the use of the bandage praised by M. Malgaigne, as it must, perforce, interfere more or less with the play of the respiratory powers.

Meeting adjourned at half-past five p.m.

At the meeting of the Academy of Sciences of May 5, only two communications were read which presented any connection with medical science. One was a letter from Professor Pirogoff of St. Petersburg, on the influence of ethereal vapours injected into the rectum. M. Pirogoff asserts that their effects are precisely similar to those of the inhaled ether, and confirms the remarks already made on the same subject some

months since by an interesting communication. The other communication was a statement of constant of the diseases and deaths caused in the towns of Bollwiler and Feldkirch by the excavation into marshes of excavations rendered necessary by the construction of the railway from Strasbourg to Bâle. M. Doltus Ausset, the author of the letter, states that in Bollwiler, a city of 1400 souls, the gradually increasing proportion of ague has been the following, since the opening of the railway in 1841:—

1842,	36 cases of intermittent fever.
1844,	168
1845,	743
1846,	1866

Within the same time, the yearly mortality increased from 86 to 54. The same results were observed in Feldkirch, where they were even more striking on account of the smaller number of inhabitants.

EPIDIDYMITIS.—In a former number (see *Medical Times*, vol. 14, p. 342) we published M. Ricord's views with respect to the diagnosis of gonorrhœal epididymitis from orchitis. We have heard recently a clinical lecture by Professor Velpeau which induces us to return to the subject. The distinct crescentic hardness of the epididymis, the preservation of the natural resiliency of the testis, the freedom from adhesion with the skin of the scrotum, and the generally happy issue of the cases, are the leading features which characterize gonorrhœal testis, which must distinguish it from real orchitis. We cannot, therefore, possibly admit with the learned professor of La Charité, that between orchitis and epididymitis a difference of name is the only one which exists. Dr. Ricord points out in the diagnosis of hernia humoralis three causes of error which it may sometimes be difficult to avoid. The first is an anatomical condition frequently met with, and easily recognised, and consists in the epididymis being placed in front of the testis, instead of occupying its usual position behind the gland. In the second anomaly, an error may lead to the most serious consequences. It sometimes happens that the testis is retained above the abdominal ring in the inguinal passage, where it may become the seat of epididymitis and give rise to most of the symptoms of bubo. The region occupied by the tumour, the semi-fluctuation of the testis, the extreme pain on pressure, sometimes even a slight blush of the skin,—all these circumstances recurring together might certainly mislead the surgeon, and induce him to make an incision into the tumour—an unfortunate result which will readily be avoided by a glance at the scrotum. A third and analogous cause of error will be found in the possibility of the testis occupying the perineum, in consequence of elongation of the chord, or of other causes not clearly known. In this region, again, the presence of the painful gland, and its deceptive fluctuation, might induce the belief in the existence of perineal abscess, and the performance of an uncalculated and injurious incision. The frequency of effusion in the tunica vaginalis, in cases of epididymitis, has led Dr. Rochoux to consider this disease as constituted merely by the inflammation of that serous membrane, "vaginaitis." But the fluid secreted during hernia humoralis is transparent, and contains no fibrinous deposits; we cannot, therefore, look upon this opinion as correct. This liquid effusion seems to be entirely of the "passive" order, and its quantity varies from a few drops to several ounces. Its pressure on the inflamed organ is often productive of intense suffering, and its removal by a small puncture causes in these cases such instant and complete relief, that Professor Velpeau converts the practice into a precept, and a mode of treatment of gonorrhœal testis. In more than 150 cases, M. Velpeau has now employed the method with the most beneficial results, not only when serous effusion was present, and when its removal might be thought desirable, but even when no liquid existed in the tunica vaginalis, and when the puncture served only to withdraw a few drops of blood. The

pain of the incision, says M. Velpeau, is as nothing when compared to that consequent upon the application of leeches to the part, and the danger of wounding the tunica albuginea or the testis is unimportant. M. Ricord recommends, as prophylactic measures against the disease, the use of a suspending bandage during gonorrhoea, and the early treatment of all cerebral discharges and irritations, epididymitis seldom occurring before the third week of the existence of urethritis. For the actual treatment of hernia humoralis, Dr. Ricord advises leeches, poultices, and mercurial frictions, during the first period, and compression with strips of adhesive plaster during the second. As counter-indications of compression, M. Ricord mentions the late stage of the malady—inflammation "en masse" of the spermatic cord, or abundant effluvia not evacuated from the cavity of the tunica vaginalis.

HOPITAL COCHIN.

CHRONICITY OF THE LUNG; CURE.—BY M. NONAT.

M., aged fifty-six, a man of weak constitution, was admitted into hospital on January 25. Since ten days he was suffering from general illness, chill, and loss of appetite; three days before admission an acute pain set in under the right breast—cough and a rusty expectoration appearing at the same time. On admission the pulse was found at 110; skin hot; cough frequent; bowels confined. Percussion and auscultation demonstrated the presence of hepatization of the two lower thirds of the right lung (dulness, soufflé, &c.); twelve ounces of blood were immediately removed from the arm. On the morning of the 26th, respiration seemed somewhat more free, but the pulse remained at 116, and the physical signs were the same as the preceding evening. Venesection was again repeated morning and evening (twelve and eight ounces). The next day some improvement was noticed; the pulse had fallen to 98; the soufflé was less intense, but no vascular murmur was distinguishable in the supra spinal fossa. In the evening, the amendment not having increased, the venesection was again resorted to. During the two next days the symptoms underwent considerable amelioration, although the superior part of the right lung still remained dull on percussion, and impervious to air. In the other parts of the viscus the bronchial respiration had been replaced by the "crepitation redux." The expectoration during the ensuing days acquired a characteristic fecidity, and all the physical signs of a cavity showed themselves in the superior lobe of the lung. The pulse descended to 92; the face was pale and earthy; wine and bark were prescribed. In the space of ten days the sputa lost their odour, and the patient recovered gradually up to February 18, when he was discharged, still presenting in the region corresponding to the spinous process of the scapula all the physical signs of a pulmonary excavation.

This case is considered by M. Nonat to have been one of gangrene of the lung; it seems to us that such a diagnosis rests only upon the formation of a cavity and the fetor of its contents, two circumstances which might be coupled with a more frequent and less fatal consequence of pneumonia than gangrene; we refer to acute abscess. The almost constantly fatal termination of gangrene of the lung induces us to imagine that such may have been really the case, the fetid expectoration so constant in gangrene of the respiratory organs not being confined to that disease; but appearing also under other circumstances. We are aware that in general the frequency of pulmonary abscess is not admitted; but we are supported in the contrary opinion by the authority of Gendrin and others. In the present instance the progress of the case, its rapidly favourable termination, the signs derived from auscultation, can leave no doubt whatever of the fatal termination of a circumscribed abscess. Was it a gangrenous cavity?—that is the only question, and we cannot think the fetor of the expectoration a sufficient or an absolute proof of the fact.

D. McCARTHY, D.M.P.

The Use of Inoculation in Syphilitic Bubo.

Suppurating buboes. Mr. John Hamilton, surgeon to the Richmond Hospital, Dublin, observes, generally present themselves in two forms: either in an oblong tumour over the centre or inner third of Poupert's ligament, superficial and freely fluctuating from one end to the other; the integument red and thinned nearly equally over the whole swelling, with nothing like well-marked pointing. It is best to open this bubo through its whole length. The second form is rather more deep-seated, of a rounder shape, with a hard base, the fluctuation in the centre, and there is more decided pointing. Here the opening with caustic alkali is most beneficial, allowing, when the slough separates, a free exit to the matter, and setting up a change of action in the part which tends to the dissipation of the indurated basis. A superficial bubo often heals, after opening, in a few days, but in other cases the most anxious part of the treatment begins. After opening, the wound may assume a chancreous character, and, in order to ascertain its real nature, take a portion of matter for the purpose of inoculation. If this should produce a specific pustule and ulcer, the patient, besides careful local means, should be subjected to mercurial treatment, as the most effectual and rapid way of healing the sore, and ridding the constitution of the virus; but, if no specific ulcer follow inoculation, the bubo may be treated by simple local applications.—*Dublin Quarterly.*

Placenta Prævia.—Dr. Tyler recommends the following course of practice to be adopted in all cases of placental presentation, where the practitioner has been in attendance from the commencement of the hemorrhage:—In cases of partial presentation, to rupture the membranes immediately, and evacuate the uterus of all its fluid contents. After the escape of the liquor amnii, if vigorous uterine action should not ensue, to endeavour to promote it by friction over the fundus uteri, the application of a binder, the administration of the ergot of rye, or the use of galvanism. In complete placental presentation, when the os uteri is rigid and undilated, never to attempt extraction of the placenta through it in that state, but to plug the vagina carefully by means of a soft sponge, previously steeped in cold vinegar and water. As soon as the os uteri is sufficiently dilated to admit the hand, to seize a foot and deliver cautiously. Should there be no doubt of the death of the child, the head presenting, to deliver by the crotchet after lessening the head. The cessation of the hemorrhage after the extraction of the placenta being attributable to the entire escape of the fluid contents of the uterus, thus allowing the child to press against the bleeding orifices of the vessels, in certain cases the placenta might be pierced with a catheter to allow the waters to escape. This operation is applicable when the feet present, or when craniotomy is decided on.

Microscopical Observations on Ichthyosis.—M. Nicolucci has made the following observations of this disease in a woman aged seventy, and who had been afflicted for five years. The scales which had detached themselves, seen with the naked eye, appeared to resemble shagreen; viewed on their adherent aspect, they appeared to be areolar; viewed on their perpendicular aspect, they appeared to consist of small columns, one extremity of which rested on the skin, the other forming the superficies of the eruption. Under the microscope, the same columns were observed to be tubular, and united by some intermediate substance. The investing membrane appeared destitute both of cells and fibres. In the interior of the tubes were seen cells of 1-60th to 1-100th of a line in diameter, with nuclei of 1-240th of a line; each nucleus contained a nucleolus. Of these cells, some were oblong, others many-sided; each contained from one to five nuclei. The intertubular substance was composed of cellules of 1-100th to 1-160th of line in diameter, with nuclei, but no nucleoli. This substance, as well as the tubes, became transparent under acetic acid. The preceding results appear to show that the new production

of ichthyosis has a greater affinity to certain horny growths than the implication of the epidermis alone.

Chorea.—Dr. Graves asserts that, having tried the sulphate of zinc in certain spasmodic diseases, no other single remedy is so generally useful. The sulphate of zinc may be given simply dissolved in rose-water, in half-grain doses, repeated often in the day. When tolerance of the salt on the part of the stomach is obtained, it will be often borne to the amount of ten or fifteen grains in the day; but the effects must be studied, and the smallest quantity used that will ensure a cure.

Psoriasis.—When this disease affects the scalp and ears, back of the neck, and forehead, Sir Philip Crampton adopted with success the following treatment:—A sixteenth of a grain of corrosive sublimate, dissolved in half a drachm of spirit of wine, is to be taken three times a day, in four ounces of a mixture composed of equal parts of infusion of yellow bark and decoction of sarsaparilla, together with Donovan's liquor cinchoe and the fluid extract of sarsaparilla. With this internal treatment he applies to the part dilute citrine ointment, with the addition of one-third of ung. ceræ alba. The above internal remedies are often useful in scrofulous ophthalmia.

Cod-liver Oil in Struma.—Under the influence of this oil, according to Dr. Graves, the enlargement of the cervical glands in young persons of a scrofulous habit frequently disappears, and the tendency to the formation of phthisis and the recurrence of strumous hemoptysis is occasionally overcome.

Traumatic Tetanus: Administration of Ether.—Mr. Broughton, of Dobercross, near Manchester, amputated the arm of a man, below the elbow-joint, in consequence of a severe injury. One week after the operation, symptoms of tetanus manifested themselves, which for two days were treated with turpentine as an enema, calomel, opium, and belladonna, without any of the remission of opisthotonos. The inhalation of ether was then tried, which soon affected the system, and immediately all spasms ceased, and a comfortable sleep came on, which lasted ten minutes. When this terminated, the contraction returned, but with less violence; the ether again used with the same result; and, on the third application, he was left asleep, and could open his mouth better. The patient was most anxious to have it again, but a succession of spasms came, and before the ether could be used the man died.

Varicels.—A common precursory symptom of this disease, and not met in rubella or scarlatina, is lumbar pain. The first pustules are usually observed on the upper lip, cheeks, and forehead, frequently on the velum palati, before any other place. The palatine pustules run their course more rapidly than others, and arrive first at maturity.

Camphor in Incontinence of Urine.—M. Guérard has treated a case of incontinence of urine, apparently arising from phlogosis of the neck of the bladder, with enemata containing four grains of camphor dissolved in yolk of egg, and mixed with a little water, so that it might be retained in the rectum. This removed the disease for some time, but, it having returned again, it was once more removed by the same treatment, and the cure seems to be permanent.

Diagnosis of Tumours.—M. Kün, professor of physiology in Strasburg, has invented an instrument which seems likely to be very useful in the diagnosis of various kinds of tumours. It consists of an exploring needle, having at its extremity a small depression with cutting edges. The instrument, plunged into the tumour to any depth, extracts a minute portion of the tissue of which the various layers are composed. In this manner a microscopic examination of the tumour can be practised on the living subject, and its nature ascertained before having recourse to an operation.

Excision of the Head of the Femur.—Professor Textor, of Wurzburg, has performed this operation with complete success on a boy ten

years of age, labouring under caries and spontaneous luxation of the hip-joint. Only two similar cases are on record: one by White, the other by Ferguson. Textor and Ferguson cut through the bone below the small trochanter. The patient of the former now walks without crutches.

White Oxide of Antimony in Pleuro-Pneumonia.—M. Roestan has treated a very severe case of this disease (in which bleeding was inapplicable, and tartar emetic caused violent vomiting) with white oxide of antimony, in doses of half an ounce daily. It was well tolerated by the stomach, and the disease under its influence conducted to a favourable termination.

Spontaneous Rupture of the Uterus in the third or fourth Month of Pregnancy; Absence of the Os Tenuis, &c.—A young female, aged seventeen, was seized with violent pain accompanied with vomiting and faintness, and after a short time expired. Upon a post-mortem examination, the abdomen was found filled with coagulated blood, which surrounded a fetus of the third or fourth month; uterus ruptured along the right side, from the fundus to near the neck; left ovary and fallopian tube entirely wanting; the right fallopian tube entered the uterus near the neck, and the ovary was lower than natural. On examining the neck, there was no trace of an os tenuous, nor could any communication be discovered between the uterus and vagina. The preparation is placed in the Buffalo Medical College.

Aneurism spontaneously cured.—A man, after bleeding, had a tumour form over the place of puncture, which was soft, pulsating, subsiding on pressure, and filling again when the pressure was removed; which ceased to pulsate when the brachial artery was pressed, and in which the bellows sound was distinctly heard. The patient objected to an operation, and in three months from the injury, the tumour had spontaneously decreased to the size of a filbert, movable and incapable of diminution. This unexpected result is attributed to the quiescent state of the limb.

Condition of the Urine in the Insane.—Dr. Breitenmeyer observes that the urine may occur in two opposite conditions in insane persons: first, it may be pale, deficient in solid constituents, especially in uric acid and its combinations; secondly, exactly opposite to the former, being high-coloured, rich in solid constituents, especially in uric acid and the urates, and consequently of a high density in idiots and epileptics. Urine of the first variety has a great tendency to become alkaline, especially in maniacs. The tendency is less marked in melancholics. Decomposition of urea is the cause of this alkalinity: it occurs, therefore, more rapidly in summer than in winter. The more tendency there is in the urine of melancholics to become alkaline, without any organic disease of the spinal cord or brain to account for it, the greater liability is there of the case becoming worse, and passing into one of mania. In the second variety the urine has little tendency to become alkaline: indeed, it often retains the acidity for a considerable time longer than does the equally acid urine of healthy persons.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, April 27.—J. M. Abbott, Esq., F.R.S., President.

ON THE COMPARATIVE WEIGHTS OF ORGANS IN NATIVES OF INDIA, AND EUROPEANS.

By E. A. Parkes, M.D.

Assistant-Physician to University College Hospital, and late Assistant-Surgeon to H.M. 84th Regiment.

The results contained in the paper are derived from twenty-three observations in male Asiatics, chiefly Hindoos, and thirty-eight European soldiers. The tables show a considerable preponderance of weight, on the part of the Euro-

peans, in the following proportions (the weights in the Hindoos being taken as unity): of cerebrum, as 1 to 1.1-6th; the cerebellum, as 1 to 1.1-6th; the right lung, as 1 to 1.1-7th; the left lung, as 1 to 1.1-6th, nearly; the heart, as 1 to 1.1-6th; the liver, as 1 to 1.1-6th; the spleen, as 1 to 1.1-6th; the pancreas, as 1 to 1.1-6th; the right kidney, as 1 to 1.1-6th; and the left kidney, as 1 to 1.1-6th.

As the weight of organs in the same race and sex varies according to the age and the height, it is necessary to reduce these conditions to the same standard. (Tables are given of these particulars.)

Age and height being equalized, the disproportion between the two races is reduced, but not entirely got rid of. Assuming the weights in the Asiatics to be as unity, they are, to the Europeans, as follows: of the cerebrum, as 1 to 1.1-9th; the cerebellum, as 1 to 1.1-11th; the right lung, as 1 to 1.1-9th; the left lung, as 1 to 1.1-11th; the heart, as 1 to 1.1-6th; the liver, as 1 to 1.1-7th; the spleen, as 1 to 1.1-6th; the pancreas, as 1 to 1.2-5th; the right kidney, as 1 to 1.1-6th; and the left kidney, as 1 to 1.1-6th, nearly.

After considering these points at some length, and deciding that the differences between the weights in Europeans and Asiatics are not attributable to differences of height, age, or unfavourable hygienic conditions, on the part of the latter nation, the weights in the Asiatics are examined more in detail.

The author observes, that the numbers examined are so few that he should have hesitated to bring them before the society, but that, first, he was unaware of similar observations having been made, and he therefore hoped his cases might afford assistance to any one who had the opportunity of pursuing the subject; and secondly, that though the observations are on so limited a scale, he was struck by the great uniformity of result.

As from the tables given in the paper it appears the inferiority of the weights of the organs of Asiatics is not attributable to differences in age or height, the author thinks it a fair inference, that the form and general conformation of the body—such as the respective length of the trunk and extremities, &c.—are the circumstances which exert the greatest influence on the size and weight of the several organs, i. e., the inferiority in weight is explained by reference to inherent differences of race and nation.

What, then, is the cause of the difference? Is it to be presumed (the author inquires) that this is acquired from the peculiar mode of living, the usual food, the accustomed occupations, and the several influences of climate and situation? These points are dwelt upon at some length, and the author concludes by expressing a hope that the medical officers of the army, whose field of observation lies within the tropics, will shortly supply us with additional means of deciding upon the correctness and importance of his few observations.

Dr. Parkes replied to the chief of the observations made. All the persons on whom he had made his inquiries were vegetable feeders; they were prisoners, and allowed only the gaol diet, which consisted entirely of vegetable matter. The majority of these persons, too, were of a high caste, and had, probably, never tasted animal food. He was aware that many of the lower classes in India did indulge in animal diet. It was to be remembered that the liver and kidneys in the persons he had examined were less in proportion to their size, whilst the cephalic and thoracic organs were not so.

ON FRACTURE OF THE LOWER EXTREMITY OF THE RADIUS.

By Professor Fenger, of Copenhagen. [Translated from the Danish by H. M. Shaw, Esq., and communicated by Dr. Hodgkin.]

The author commences his paper by deprecating the love of display which he attributes to men of science in the present day, and which, he says, too often renders discoveries, in their estimation, secondary in importance to the notoriety of the discoverer. To this cause he assigns the want of interest with which the ob-

servations of Dupuytren and Malgaigne on fracture of the radius were first received. He then directs attention to a tabular view of 140 cases of fracture which came under his notice during nine months that he was on duty as surgeon to the Royal Frederick's Hospital, which it appears that thirty-one were of the radius, and only one of the ulna, and from this table he infers that the radius is more frequently fractured than any other bone, and more than twice as often as the fibula. The difficulty attending the diagnosis of the fracture, and the frequency of its confusion with sprains of the wrist. Under the head of "Causes" of a peculiar fracture, the author gives another view of the thirty-nine cases which came under his notice, from which it appears that the accident was rather more frequent in men than in women, and that age predisposes to this lesion. In treating of the symptoms of fracture of the radius low down, the author associates great importance with the deformity, as a diagnostic sign of the injury in question may be distinguished from sprain. The straight line extending from the radius and metacarpal bone of the fourth finger appears to be broken in two places: first, closely over the styloid process of the radius; secondly, over the carpus and metacarpus. This line is hereby divided into three parts, of which the superior and inferior portions are parallel, and the centre and shortest one forms an angle with the other two, thus forming a figure something like the letter Z. Of these two angles the upper one is always present in this fracture, and remains unchanged by any position of the arm. Fracture of the lower extremity of the ulna, extravasation into the articulation, and luxation of the radius from the ulna, constitute the complications which Professor Fenger has met with in cases of fracture of the radius low down. In the greater number of the cases the author found that the fracture was oblique, beginning on the palmar side of the lower end of the radius, a little above the articulation, and proceeding upwards towards its dorsal aspect, where it terminated from an inch to an inch and a half above the joint. He believes, however, that the fracture is more often transverse than is generally supposed.

After commenting on the splints and treatment recommended by Dupuytren, Strohmeyer, Velpeau, and Blandin, and stating his opinion of their insufficiency in difficult cases, the author proceeds to describe the plan of treatment he has found most successful. He states, that as the deviation occurs in a curve, with its centre upon the fracture, it is desirable to counteract the deformity by extension acting in a direction according to the tangent of that curve. This end he thinks is best attained by acting through the medium of the hand and of the capsular ligament which is attached to the lower end of the radius. The hand is first to be brought into a position of strong flexion, and the forearm is then placed on an oblique plane, with the carpus highest, the hand being permitted to hang freely down the perpendicular end of the plane. The tendons of the extensor muscles are thus brought into a position which enables them to assist in keeping the reduced fragments of the bone in proper relation. Where the deformity requires it, the displaced lower fragment is to be pressed into its position by the thumb of the operator, after sufficient extension has been made, and when the hand is bent on the forearm. The patient is to be kept in bed, but the hand is not confined, the seat of fracture being covered only by an evaporating lotion. Out of the thirty-nine cases under the professor's care at the Frederick's Hospital, he failed but in one in effecting a cure. He has found a similar plan of treatment equally successful in fractures of the radius higher up the arm.

Mr. Partridge presented a dissection of a fracture of the lower extremity of the radius, the fracture having passed obliquely through the lower end of the bone, cutting off the styloid process, and passing into the articulation. The

man had been admitted an out-patient in King's College Hospital, with comminuted fracture, which was treated on the usual principles, but in a few days after the accident he came into the hospital, abscesses having formed, and pieces of bone having come away, and he had ultimately been obliged to perform amputation of the arm. Mr. Partridge believed that the fracture was most frequently oblique, and considered it as one very difficult to treat satisfactorily.

Mr. Shaw was aware that this fracture had been termed in Dublin, Colles' fracture, having, many years ago, been described by that distinguished surgeon; but until the year 1834, its pathology had remained comparatively unknown. The frequency of its occurrence, and the difficulty attending the diagnosis, had been admitted. When existing in a slight degree, it was liable to be mistaken for a distortion or dislocation of the wrist, and when in a greater degree, for a luxation of the same. In the London Hospital, from which alone he had been able to procure statistical data for any lengthened period, the fractures of the radius, ulna, and of both bones together, were reckoned as fractures of the forearm, without distinguishing them from each other. Knowing, however, how very much the number of fractures of the radius predominated over those of the ulna, or of both bones together, the frequency of this fracture might be easily conceived. In 1812, there were treated at the London Hospital 810 fractures, of which 163 were of the forearm. In 1813, there were 899 fractures, and 156 of the forearm. In 1846, 952 fractures, 200 of which were of the forearm; and in 1846, there were 954 fractures, with 176 of the forearm. In the five months, from May to October, 1846, at the King's College Hospital, there were treated eighty-four fractures, fifteen of which were of the forearm, twelve of radius, and three of ulna. Acknowledging, then, the frequency of this fracture, and the repeated failures attending its treatment (Velpau cures but thirty out of fifty), thus causing a partial, if not total, loss of the use of the hand and fingers to a great number of our fellow-beings, it will be readily conceded that any rational plan, by which a more favourable result may be attained, is worthy the notice of the profession. As it had been remarked by Mr. Buss that it would be no easy thing to keep patients so long in bed with this fracture, Mr. Shaw thought that a splint, in which the arm could be supported, permitting the hand, at the same time, to hang freely down, or rather, to be fastened down, might be used, and the patient could, under certain restrictions, be allowed greater liberty. To the other objection, that the patient would not be able to sustain the weight of the hand so long a time hanging down as would be necessary for the consolidation of the fracture, he remarked that this position seemed to him the most natural—at any rate, less constrained than in starch bandages, Dupuytren's splints, &c.; and that the patients, in the numerous trials made by Professor Fenger, had not experienced more difficulty than might be reasonably expected under such circumstances.

A CASE OF LARGE SECONDARY PROSTATIC CALCULUS REMOVED BY PERINEAL INCISION.

By T. HERBERT BARKER, M.B. (Lond.).

Fellow of the Royal Medical and Chirurgical Society; M.R.C.S.L.; formerly House-surgeon of University College Hospital, London.

John M., of Harrowden, near Bedford, aged twenty-six, sent for me on the 26th of Oct., 1843. He was labouring under complete retention of urine, and complained of considerable pain in the urethra and perineum. On examination, the urethra was found to be very cedematous, with a small opening on its under surface towards the left side, about three inches from the extremity, from which a small quantity of purulent

fluid was discharging. This opening first made its appearance four years ago, followed by the escape through it of a considerable quantity of urine; for the last twenty-four hours the flow had ceased through this opening.

The perineum presented some tumefaction and slight redness of the soft parts. By pressing the centre, near the anus, a deep-seated hardness could be felt; and on attempting to remove this hardened base from side to side, crepitation could be detected, as if produced by the limited movement of calculi firmly impacted together. On introducing the finger into the rectum, considerable enlargement was felt in the region of the prostate gland, and similar crepitation was also felt as far as the finger could reach in that direction. On introducing a probe into the fistulous opening, it passed readily about an inch and a half, backwards and inwards, towards the urethra, but it could not be brought into contact with any hard substance.

He had laboured under incontinence of urine since he was four years of age; had been a patient in the infirmary without any relief; had never suffered severe pain, and the urine had always flowed through the natural channel till the formation of the fistulous opening, four days ago.

He was directed to maintain the horizontal position, to use fomentations of warm water to the perineum, and to take simple aperients. Next day no improvement, and an attempt to pass the probe further backwards through the fistulous opening produced the same result.

Operation.—The patient was placed in the position for lithotomy; the perineal integuments were rendered tense, and an incision made through them, together with the superficial fascia, two or three lines to the left of the raphe, commencing about two inches and a half from the anterior margin of the anus, and terminating within half an inch of this margin. On introducing the point of the finger into the incision, the calculus could be readily felt, and was cut down upon with the point of the bistoury, and the intervening soft parts were divided upwards and downwards, to the entire extent of the first incision. The several portions of the calculus were firmly wedged together, and it was impossible from the size to remove it *en masse*. A lateral movement with the thumb and finger loosened the anterior narrower part of the calculus, which was removed, and some of the posterior and broader portion was disintegrated. Several portions were brought away with the finger, others with the forceps. After all were removed, the parts were sponged, three points of interrupted suture were introduced, the perineum covered with lint, and the patient put to bed. Ordered spare diet, with a mild opiate draught at bedtime.

Next day he was free from pain, but the urine accumulated in the cavity and escaped between the sutures. Very slight tumefaction of the perineum, and the oedema of the penis somewhat subsided.

The case having gone on favourably, on Nov. 13 a catheter was introduced into the bladder, and secured. Two needles were passed through the parietes of the unhealed parts of the incision, which were brought closely together by the twisted suture. On the 16th the urine dribbled through the urethra, and the needles were removed. From this period the wound healed soundly, but he could only retain about half an ounce of his water at a time, which passed, however, by the urethra. Eight weeks after the operation he went to work.

The calculi were twenty-nine in number, and weigh 1681 grains. They are of a whitish colour and porcelainous lustre and hardness. The chemical examination showed that they were identical in composition with the concretions occasionally found in glandular structures, consisting of phosphate of lime, with a rather larger proportion than usual of the ammoniac-magnesian phosphates. Up to the present time the patient continues free from further calculous deposit.

REVIEWS.

A Treatise on Fractures in the Vicinity of the Joints, and on certain Forms of Accidental and Congenital Dislocations. By ROBERT W. SMITH, M.D., M.R.I.A. Dublin: Hodges and Smith. 1847; pp. 314.

The author, in his preface, states that the object which he had in view, in submitting his work to the profession, was not to present a systematic treatise upon the extensive subject of fractures and dislocations, but to direct attention to that most difficult portion of it—fractures in the vicinity of joints, especially those of which himself had most experience, and the differential diagnosis of which he had found to be attended with the greatest difficulty. It is no easy task for a surgeon to write upon some of the most obscure and difficult points of practice so as to afford information to his readers, and secure applause for himself; and very few there are, who have talent and education so happily blended as to give them a permanent nobility in the republic of literature.

Dr. Smith has, in the work before us, proved himself a clever surgeon and a respectable author: for the difficult subjects on which he treats have evidently been well studied, and he has written in a style concise, neat, and devoid of obscurity. In the chapter "On the Diagnosis and Pathology of Fractures of the Neck of the Femur" he has some good remarks in reference to the general symptoms, the causes of the accident, and that which renders correct diagnosis very difficult. His remarks on impacted fracture are well worth particular consideration. He says in reference to this fracture, "In many cases the symptoms are so obscure, and so much at variance with those with which we are familiar as denoting the existence of the more common forms of fracture of the neck of the thigh-bone, that more than ordinary caution is requisite to enable us to avoid committing an error in diagnosis, and pronouncing that the injury which the joint has suffered is merely a severe contusion which will not be followed by a serious impairment of the functions of the limb; whereas the truth is, that shortening and lameness are the inevitable and permanent results of even the slightest degree of impaction of the broken cervix into the shaft of the femur. This particular form of fracture is the only one the diagnosis of which is attended with difficulty, for it rarely happens that the limb is shortened to the same extent as in the ordinary examples of extra-capsular fractures: in general the amount of retraction is nearly the same as in cases of fracture within the capsule. Between these two forms of injury, therefore, the shortening of the limb is not available as a means of differential diagnosis." Nor is there crepitus, "because of impaction of one part of the neck of the femur into the cancellated tissue of the shaft, and from the fibrous and tendinous structure which invests the whole of the region traversed by the second fracture, which is always present, that the detached portion of the trochanter in general moves with the shaft of the bone; and cases have occurred in which the patient has not only raised himself from the ground after the fall which caused the fracture, but has even walked a considerable distance, bearing his weight on the injured limb. In ordinary fractures of the neck of the femur there is no difficulty in ascertaining the nature of the injury; but in the particular form of fracture now alluded to, the whole expression of the limb is well calculated to deceive: it does not present a completely powerless aspect, there is some command over its motions, no very great degree of shortening, and sometimes the patient is seen to maintain the limb resting fairly on the heel, turned neither inwards nor outwards, and is able without much pain to flex the leg on the thigh, and the latter on the abdomen. "Here," observes the author, "we have a group of symptoms by no means characteristic of fracture of the femur, but such as would rather induce us to conclude

that the injury was merely a severe contusion." Afterwards he adds, "The evidence of the existence of an impacted fracture is of a negative rather than a positive character, and may be thus briefly stated:—1. Slight shortening of the limb; 2. Slight eversion of the foot; 3. Absence of crepitus; 4. Great difficulty in all cases, and in the majority of instances an impossibility of removing the shortening of the limb by extension; and, lastly, less loss of power than in other cases of fracture of the neck of the femur."

The chapter is replete with information to the surgeon, and there are nearly 200 illustrations, which are certainly very beautiful specimens of art. "The work is a valuable addition to our professional literature, and a careful perusal of it will amply repay even veterans in the science, though they may differ concerning some matters of which the author treats."

Practical Remarks on some Exhausting Diseases, particularly those incident to Women. By Sir JAMES EYRE, M.D. 12mo. London: John Churchill. 1846; pp. 75.

This little volume contains some very sensible reflections and observations upon various forms of hemorrhage from various organs; but its chief object is to bring prominently forward a remedy in these cases, which has heretofore had many advocates, but whose virtues are still not sufficiently understood. This remedy is the oxide of silver. For several years past, this substance has been in repute as a tonic, especially in certain painful affections of the stomach, in neuralgia, epilepsy, chorea, &c.; but it has only been within the last six or seven years that its anti-hemorrhagic properties appear to have been fully tested and proved. In the hands of our author, it seems to have more than realized all the good reports made of it by previous writers: for whilst, according to his experience, it possesses all the good qualities that belong to ergot, sarsaparilla, tannin, turpentine, lead, *et hoc omne genus*; in hemorrhagic diatheses and discharges, it is divested of many unpleasant and even hazardous tendencies which we know attach to those medicines. If the oxide of silver be in reality all that our author says of it, it indeed deserves to be in much more general use than it is at present. Ourselves have often tried it as a tonic remedy, and have had every reason to be satisfied with its services; of its particular powers in arresting hemorrhages we have no experience, but we shall certainly give it an early trial.

The volume before us contains, in addition to general statements, a good selection of striking cases summarily related. With the exception of one or two of gastrodynia and pyrosis, in which the oxide of silver proved curative, the rest are mostly examples of various forms of hemorrhage, in which it was not less successful. In particular, we may mention some of hemoptysis, in which its efficacy seems to have been very decided. Our author says, in conclusion—

"It will have been observed that the dose of the oxide of silver employed by the writer in the foregoing cases never exceeded three grains a day (from one quarter to one half a grain for a dose), instead of six, as given on its first introduction; and that its employment is not recommended where febrile action exists in any considerable degree. In addition to its value in gastrodynia, pyrosis, hemoptysis, hematemesis, and in the first and second classes of menorrhagia of Dr. Fleetwood Churchill, it will be found to be productive of infinite benefit in restraining, when absolutely necessary, hemorrhage proceeding from the intestinal canal, obstinate chronic diarrhoea, colliquative perspirations, hæmorrhæa, and other maladies, in the treatment of which the writer is at present testing its efficacy."—(P. 76.)

ROYAL COLLEGE OF SURGEONS.—Gentlemen admitted members on Friday, May 7:—S. Melrose, J. Rushforth, G. Davis, T. Littlejohn, J. Prowse, D. Hope, H. Hart, R. Capron, and G. Milburn.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carfax, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

The MEDICAL TIMES is sent on the day of publication, free by post, to all parts of the United Kingdom, and to most of the British colonies.

Sir George Ballingall's unanswerable Lecture on Military Punishments, in last week's Medical Times, was from the "Monthly Journal of Medical Science."

Dr. J. C. Hall's suggestion will be considered.

Mr. A. W. Close, Manchester, is thanked for his communication.

Mr. Evan Thomas, Carlisle.—The paper has been received.

A Thorough Reformer, Bradford.—The fears which are expressed are groundless, as the misrepresentation of public opinion will fail to accomplish the purposes intended.

A Constant Reader.—We have so many communications with this signature, that it will be really a favour if some of our correspondents would write under another name. We have a knowledge of the parties mentioned.

Mr. A. Wear.—A member of the Edinburgh College of Surgeons practising in England as an apothecary without a license is liable to a prosecution. The College of Surgeons, London, requires the candidate for a diploma to have been five years in the acquisition of professional knowledge; the Apothecaries' Society five years' apprenticeship.

Inquirer.—A correct report of the Humidian Oration, delivered by Mr. Green, appeared in the Medical Times.

Paul Pry.—Diploma-mongering is not quite so fashionable as it was, and we are unable to say what is becoming of Dr. Bond. The Giesen parchment is at a discount.

A Member of the National Institute.—The deputations to the Secretary of State were all strongly opposed to the new Bill. We know of no members of the Institute favourable to it.

Mr. B. Gough.—The offer is respectfully declined. The article would not suit our pages.

A Young Surgeon.—Studying disease at the bedside will be a more dignified and useful employment than that referred to.

A. B. C.—Those who were in practice prior to 1815 are legally qualified, though they do not possess a diploma or license.

Mr. Amos.—Students are not now entirely excluded from certain institutions where they have opportunities of studying mental disease. There is provision made at Guy's for a certain number.

Anti-humbag.—We are obliged for the compliment, but "Timeo Danaos," &c.

J. W. Stratford.—We cannot engage to insert all the communications received. Certain things may interest special parties, but may be very unsuitable for a medical journal.

M. D., Bristol.—A new Pharmacopæia is necessary. The College of Physicians is preparing one.

A Student, Glasgow.—John Hunter was a general practitioner. His museum is in the College of Surgeons, London.

Mr. Barron.—The Medical Times is always sent regularly to the address.

T. C. D. will find his expectations answered at a very early period.

Emigrant.—The American colleges, we believe, will admit English medical men to an examination, on showing their diploma or license.

If an Essex Surgeon will favour us with his name, we may, perhaps, be more inclined to comply with his request.

Mr. Walter Lewis, Oxford.—The paper is under consideration.

A Candidate is a little too severe.

Mr. Franz Thimm.—The communication is received.

Mr. J. Dixon has our thanks.

Mr. L. Rugg's case will be considered.

J. P. (Southall) considers the case of Miss S., reported in last week's journal, as one to be ranked with the numerous instances we meet with of the judicious administration of narcotics and sedatives.

A Correspondent sends us an analysis of the Twelve. But it would be ill applying the space to make it a "Registration Bill" of persons designated as "political tools," "illegal practitioners," and "paid servants."

A Pupil.—The membership of the College of Surgeons is undoubtedly a lower grade than it was a few years ago.

M. D.—There is really not a shadow of chance for the new Bill. Ministers are pledged to oppose it.

H. J., Bedford, should apply directly to the Secretary.

A General Practitioner suggests (we think unwisely) that the meeting at the Freemasons' Tavern should be used as a model for other places against the Bill, viz.,—"each gentleman present contributing sixpence for the expenses, and thus allowing five shillings for the room and one shilling for the waiter." Whichever of the twelve carries the purse, there can be no fear of treason.

We have received a Wakefield series of resolutions. Surely the four or five gentlemen who appear to have joined in them have not lately been in the exercise of their customary discriminating faculties. We are sure Mr. Rogers would be sorry, on after reflection, at our compliance with his request. If he persist, the resolutions can be published as advertisements.

Qualification.—We have no time to work up the divisions of poor-law qualifications. They may be found in past numbers of the Medical Times.

A General Practitioner will do well with the work of Guy, and the last edition of Beck.

We shall make early provision for the papers by Dr. Brown and Mr. Kay.

We propose to give a notice of Dr. Buchanan's work in our next.

We have received communications and letters from Mr. Norman, Mr. Thomas, Mr. J. Lloyd, Mr. M'Donogh, Mr. Wm. Smith, Dr. Brown, Mr. Kay; Mr. Thompson, Newark; a Constant Reader, York; Mr. Tison, F.R.S.; Mr. Bulley, of the Royal Berkshire Hospital; Mr. McClinton; Mr. L. Rugg, Mr. Barron, a Pupil, Dr. J. C. Hall, Mr. A. W. Close, Mr. Evans, a Thorough Reformer; Mr. A. Wear, M.D.; J. W., Mr. W. Lewis; H. J., Bedford; Mr. King; Dr. Wright, Birmingham; Mr. B. Gough, a Candidate, Inquirer, Mr. Amos, an Essex Surgeon, Anti-humbag, a Juror, Dr. Willshire, Mr. Isaac Brown.

THE MEDICAL TIMES' PRIZES FOR THE BEST REPORTS OF MEDICAL AND SURGICAL CASES.

The results of our last Prizes have been so far encouraging that we propose for Professional Competition, for the year 1847, the following Prizes:—

Twenty-five Guineas for the twelve best reports of original cases in hospital or dispensary practice.

Ten Guineas for the twelve reports of original cases, as above, second in merit.

Five Guineas for twelve reports of original cases, as above, third in merit.

In offering these prizes we repeat that our aim is, as in other matters, is to promote the SCIENCE of our Profession. The groundwork of the best part of our practical science and of most of our subsequent Professional worth is laid down in our studentship; and the great and the only true teacher of the student must ever be—hospital practice. Lectures and books have their use; but it is by the bed which holds a human being, with the joy of health or the pain of disease, the chance of life or the peril of death, depending on the aids of science, that we acquire our true knowledge. There is then for the student no useless ear, no dull eye of the lecture-room; it is not the memory alone that is appealed to, or some abstract love of a pedantic and inapplicable lore. Every power of his mind is engaged: he is forced by the sympathies of his nature to hear and see, to observe, to reason, to prognosticate, to be EXPERIENCED: each patient's case is a volume of medical science in its most practical aspect, forced on his acquaintance for life!

The authors must be students who shall not have received any medical diploma or license.

Six of the cases are to be medical, and six surgical.

The cases must have occurred during the year; and the names of the gentlemen under whose treatment they may have principally come must be specifically mentioned.

Three arbitrators will be appointed—one surgeon, one physician, and one general practitioner—whose names will be duly announced. The decision will be on the 1st of July.

The Prize Reports will be published in succession in the "Medical Times," with the names of their authors.

They are to be sent to the Editor of the "Medical Times" on or before May 1, 1847, accompanied by a certificate from a surgeon or physician to a hospital, declaring that the writer is *bona fide* a medical student. A motto or device must be inscribed on each report, to identify the author, whose name, with a duplicate of the motto or device, must be written in a private note, which will be opened when the award shall have been made.

THE MEDICAL TIMES.

SATURDAY, MAY 15, 1847.

PROFESSIONAL REFORMATION.

"*Repulus me sibi facit.*"

MR. THOMAS WAKLEY, of Finsbury, persists in bearing his Prometheus agony of political existence with a fortitude "unblenching" as hopeless. If he were not—what of course he is—that might so dear to angels, a good man struggling with adversity—he would reel in an humble way, at least, the more touching incidents of the spectacle. What man supported by the probability of an Aristides could outface a small repulse more unshrinkingly, or outbrave public opinion more pertinaciously? It is the stolen fox, concealed beneath the cloak, eating into the heart, no feature announcing torture till death discloses what political Spartans can endure even for indifferent causes! If there were not in it, as there is, a heroism unknown to the records of ages, we should find no name for the characteristic but—lunacy.

Under difficulties and disasters that might well oppress to the earth and to favourable obscurity a more sensitive character, the Finsbury member aspires to confer on us the favour of reforming legislation. Unasked, unsought, he has taken us under the shattered wing of his protection. In remembering, our position, he generously forgets his own, and is bountiful beyond measure with a political indigence without parallel. He squanders cheques to us on banks wherein he has no effects, and is prodigal of benefits over which he has no control. His charity, neither beginning at home nor returning thither, swells in the inverse ratio of his means, and we are overwhelmed by his legislative endowments at the very moment that he is pronounced a political bankrupt. Lost as a public character, broken down, discomfited, *cut*, this is the precise moment that the defendant in the case of the Queen v. Wakley selects to play statesman for us in a senate of six hundred gentlemen, and to make statutes for citizens to whom an honest administration of the laws we have is the first necessity! How very droll! There is an anomaly about it for which a Sutherland, a Costello, or a Connolly alone could furnish explanations!

On the strength, however, of an axiom circulated for the benefit of such persons as the Finsbury member, "*measures, not men,*" we will daunt his new bill that single moment's attention which, possibly, could not be justifiably employed on its author. There are some people who will rather be kicked behind than look a gift-horse in the face before, and for their benefit we must design a brief examination which we would otherwise gladly escape.

And, first. This bill of Mr. Thomas Wakley is not the bill of Mr. Thomas Wakley. There never was a clearer case of picking and stealing. It is Graham's bill, just enough disfigured, slit, and patched, to obscure the original proprietorship. Swift talks of gipsies stealing children, and, after sufficiently deforming them, passing them off as their own. The parallel case is before us. Graham's bill has been so far crippled and disfigured that it might easily be mistaken for the natural progeny of the Finsbury member. It wants nearly every feature that should commend it to an honest senate, or a learned profession. It is born in sin, and christened in fraud. First stigmatized as a monster—when Graham's—it is subsequently stolen, and then not only disfigured, but misnamed. In its very adoption there is the stamp of a legislative audacity, brazen and matchless. A "*Registration*" Bill, it is virtually a bill for something else; and that something else, besides being a plagiarism, is defective, petty, bad. There is not one respectable quality about the measure. It is at least as base, as paltry, and as despicable in its now possessed characteristics as in its discreditable origin and birth. We look in vain throughout for a principle or an improvement—for originality, comprehensiveness, or even respectability: a few shabby, worthless clauses—made familiar by their appearance and reappearance, as inconsiderate parts of the bills of Hawes, Warburton, and Graham, constitute the whole bill—a bill which we do not hesitate to call the most singular and matchless in its history and qualities, from its denunciation in Graham's measure and cool adoption by this person, down to its last interpretation clause, of all the curiosities in the way of legislation that ever got paid a few days' visit to the reformed House of Commons.

In descending—and we feel it is a downward movement—to the details of a bill that has, indeed, nothing else for consideration, we may, as least troublesome and most expiatory, fling them into three divisions—

1. What good, or rather, what service to Wakley?

2. What good to Sir George Grey?

And last and least, what good to the profession and public?

1. Wakley undoubtedly is in the political position where he can suffer by nothing. The bill, even if twice as discreditable and trumpery, can, therefore, do him no harm. Having lived by Medical Reform—or rather by talk about and at it—for a quarter of a century—having been in Parliament a decade of years—having opposed the bills of Warburton, Hawes, and Graham—the time is come in which he may show in how profound, how comprehensive, how philosophical, and how statesmanlike a fashion he can provide for the good government and reorganization of the medical profession! Hence the great measure of 1847! The agitation for his rickety, truncated plagiarism can do him no mischief—certainly not—if it fail; if it succeed, are there not, besides its success, *three registrarships* in the patronage of the Secretary of State?

2. The Secretary of State must be remarkably ungrateful—if the measure should pass—if he deny the author the possession or sale of at least one of the registrarships: for it is difficult to conceive anything finer than the munificence with which the bill showers patronage and power on that honoured functionary. He is to appoint three registrars, whom he may remove at his own

discretion; nominate clerks and other officers *ad libitum*, who are to be removable under the same phenomena; he is arbitrarily to fix the curricula of collegiate education; at his own pleasure to dictate the amount of collegiate fees; establish his own educational regulations; nominate his own collegiate supervisors, and possess the power of practically repealing and abrogating all the statutes and charters by which the colleges examine and give licenses! For the full the Secretary of State is to be at once King, Lords, and Commons to the whole medical profession! If Sir George Grey, with such inducements, do not give the "shabby measure" a helping hand, he is less accessible to a vulgar bribe than the Finsbury representative seems to have imagined.

3. We should be the last to depreciate the advantages of registration if made, as it should be, a subsidiary portion of a complete measure of Medical Reform, and if not imposed at a higher cost than any utility that can arise from it. In the bill before us we have exactly the two defects that can alone vitiate it. The registration is not accompanied by what would give it value—and has the companionship of much that must make it a calamity.

At the best, registration is no priceless boon. The man who trafficks in it makes us these avowals:—

"Are not the qualified medical practitioners of the United Kingdom registered or enrolled in the institutions to which they respectively belong? Such undoubtedly is the fact. Thus the proposal amounts to this—that there shall be three registrars instead of seven or eight. What an improvement!"

Again he says—

"Can any system which directs the mere putting down the names of medical men in alphabetical order and in classes be attended with that relief from annoyance which has compelled them to present their petitions to the Legislature. In a word, the plan for registering the members of the medical profession in THREE CLASSES is objectionable in principle, and must operate painfully and injuriously in practice."

Without stopping to apply the language that so naturally presents itself—"Thou wicked servant—out of thy own mouth do I condemn thee!"—we may at least say, that if there be anything in these objections at any time against a registration measure, they were never so forcible as now, when the Medical Directories of Ireland and Great Britain, now annually published, give us, without cost, a fuller, better, and more accurate registration of the profession than any scheme of Parliament or the Government, however successful. It is absurd to fancy that a parliamentary register will ever, or can ever, be complete. Hundreds would never pay two pounds for an advantage which they would probably estimate as very equivocal; and thousands would never incur either the trouble or expense of the annual renewal. Certain are we that many of the most distinguished of the profession would be found out of the list, and that, as a conclusive authority, it would be found, if not null, something worse.

That the establishment of a register of this kind would be any protection against empiricism, it would be absurd to anticipate. The quack would ill appreciate the influence of the list, or the tendency of the public mind, and richly deserve "punishment" on the score of his folly alone, if he sought practice on the ground of being "registered." It is much to be feared that the distinction would run in another direction.

are several points, as regards the chemists and druggists, and the power sought to be given over us by the Secretary of State, which require to be dwelt on, but we must this week content ourselves with registering our protest against this "shabby measure" on the highest grounds the profession can take—its deadly injury to our educational interests. It is a legislative enactment of a low and bad order of doctorship. It is the establishment of a Lancastrian system of medical education. It is in fact a levelling measure of science—not raising the lowest, but depressing the highest. What has hitherto allowed the profession to maintain a deeply scientific position in society, notwithstanding the evil tendencies and influences of that bad administrative system which this bill legalises and perpetuates? What but this? That the institutions which raised the standard of qualification secured for their members and themselves a more distinguished character before the public. But when this distinction is lost sight of—the Register being everything, and the College nothing—what is there to stimulate any examining body to keep high its test, notwithstanding the loss to the exchequer? The contest will then be, not for character, but funds; and that college will think itself best which has passed most candidates, and secured most money. "*Virtus post nummos*." This influence, so exercised on the institutions, will reach the whole body of the coming profession. The question with each candidate will be, which college is easiest in its terms; and which one of the three or four medical designations can be got most easily. The Register covers a multitude of sins: his one title will serve him as well as a dozen: in the words of the bill, "medicine" for him shall mean "surgery," or "surgery" shall mean "medicine"; the whole uprising body of the public (inclusive of chemists and druggists, and cuppers and dentists, and chiropodists) have only to get one title—from any quarter, under any circumstances—to stand in the Register in equal rank with the best-general practitioner in the country!

We have here a question opened which concerns the existing profession in every way—in purse, in credit, in utility. There are already more pigs than tents: more practitioners than patients. Why lower the barrier and increase an already excessive and calamitous competition? We respectfully address this topic to the deliberate wisdom of the "twelve apostles" of the Freemasons' Tavern. We can understand that their sympathies are with the new system of medical education. Unquestionably the change would make them more at home in their profession. But then we can appeal to any vacuum in their breeches pockets: it is, we beg to assure them, powerfully on our side of the question. Messrs. Simpson and Hodson Rugg—aye, and even their Iscariot—have interests which may for once correct their judgments, and set right their sympathies. The inundation of a new set of underbred, under-educated practitioners, however agreeable otherwise, could do them no good, in a mercantile sense. It behoves them, as it behoves us also, to root out individual hopes of elevation on the general elevation of the profession. Raise the science rather than depress it: exact more rather than fewer qualifications: reward rather than discourage a thorough knowledge of our whole calling: and you will tend as much to increase legitimate and diminish empirical practice

as the measure before you tends in the opposite direction. Believe us, gentlemen—extraordinary as you may think it—the common weal is your weal; and, if one thing more than another can add to the grievances of which you so justly complain, it is that Lancastrian system of low education of which you have naturally been made the blind supporters.

THE GOVERNMENT, THE PROFESSION, AND THE PEOPLE.

THE Registrar-General has published his report of the state of the public health in the first quarter of the year 1847. That report contains facts which are both interesting and alarming, and too much attention cannot be given to them, inasmuch as they have the most important bearing upon the health, the morals, and the happiness of the people. It is only within a very few years that correct returns have been made of the mortality which prevails amongst us, and that a proper arrangement has been effected of those several diseases which have hurried to the cities of the dead such numbers of the population. These investigations were begun, and have been carried on, by medical men, and without their hearty co-operation the Government would be incapable of arriving at any correct conclusions in reference to the health and mortality of the people. It is to the honour of the profession that it was the pioneer of the work, and that without prospect of any other reward than that which benevolent actions always bring to the bosom, it has furnished the Executive with such information concerning disease and death as will compel it to come forward to the help of a suffering people. Who else could have revealed so clearly the startling truth, that while the sword has slain its thousands, fever has destroyed its tens of thousands, and that the car of this bloody Jugernaut may yet be so retarded in its course as to save an infinite number of victims from being crushed beneath its weight? The profession has sought for no aggrandizement here: but has nobly showed the public the best means of bringing physic to a discount, and how every man may become his own doctor without being chargeable with quackery.

While the Government has been compelled to admit that the health of a people is a national concern, the public have scarcely yet been roused to a true sense of their danger. If the angel of death could be seen sweeping down myriads at a stroke, he would be greatly feared, and men's energies would be vigorously employed to check his triumphs; but as he strikes here and there, and attacks his victims through the length and breadth of the land, the population have awaited their fate, hitherto, with the meekness and silence of sheep brought to slaughter. Life is but a sorry blessing, unless it is combined with health; and it is no use for us to cry "*Domine salvemur*" when we cherish around us the very means of our destruction. The people have yet to be roused. "But who," asks the *Times*, "will set about this homely work? Who will agitate it, or agitate with success?" Who? why, the members of our profession, to be sure. They who have broken up the fallow ground—who have braved the contumelious reproaches of the champions of corruption—and who, at present, without thanks, are labouring to secure for the sons of toil that blessing which is the source of wealth to themselves and their country. It is only by showing the public the manifold evils which are induced by causes over which

they have control—the mental distress which arise from the loss of friends, the poverty which is brought upon families, the numbers of children which become burdensome to society from the loss of their parents—that their prejudices will be removed, and with them every barrier to a necessary reform. Providence has been too long blamed for evils which we inflict upon ourselves. The beautiful mechanism of the human frame has little original imperfection about it, and numberless disorders with which it is afflicted are induced by the ignorance and errors of man himself. Let him understand this, and let him know that, as the plague has been driven from our country by the improved condition of the people, so, by further advancements, typhus, that scourge of masses of the humble population, may be as effectually excommunicated.

The report tells us that *fifteen thousand two hundred and eighty-nine deaths* were registered in London during the first thirteen weeks of the year: a greater number than has been registered in any previous winter since the weekly tables commenced. The district of Lewisham, and the subdistrict of Hampstead, have only added 171 to the deaths. It is observed, that in the country districts there is a fearful increase in the bills of mortality, ascribable in some places to the scarcity and dearth of provisions, want of employment, and imperfect protection which the dwellings and clothing of the poor afford from cold; in others, to Irish immigration—starving multitudes escaping from the horrors of famine in their own country, to find food, and, alas! many of them, a final resting-place—the grave.

But London, after all, seems to be the great focus of disease and death. "Instead," says the Registrar, "of its inhabitants measuring out the whole period of the present existence allotted to them—instead of death coming upon them like a sleep, when the faculties are dulled by age and slow decay—it convulses tender infancy, falls with burning fever upon man in his prime, and snatches away the mother with the babe still at her breast." In the return, the thirty-six districts of the metropolis are arranged in the relative order of their insalubrity: the city of London within the walls stands *ninth* on the list, while the City without the walls stands, with Whitechapel, the *last*—the unhealthiest of the thirty-six. In this district alone, within the short space of seven years, 5000 individuals have been consigned to the silent grave, who, if it had not been for "houses saturated with pestilential vapours, and cesses running sewers and excremental matter," might yet have been living active beings. This great city may of a truth, then, be called the grave of its inhabitants, for it has within itself much that is injurious to health and fatal to life. And what can medical skill do against the direful influence of crowded dwellings, bad sewerage, improper ventilation, and deficient food and clothing for the poor? There is not a fair field for the exercise of its powers; and disease will laugh to scorn all doctors' potions so long as it can recruit its strength from its numerous and oftentimes invisible sources. On every moral and physical ground, it seems, from the Registrar's observations, some change is desirable; and yet the Parliament evinces an unaccountable indisposition to move in the matter. Only a few days ago, Lord Morpeth introduced the subject again to the House of Commons, and, after stating the items of a modified bill, he expressed a hope that the House would allow him to have it read a second time, when there was a cry of "No!" from a few of the august senators.

Monopoly, with some, is worth cherishing more by far than precious life, when surrounded by poverty and rags and filth. But the profession does not say "No!" to any efficient measures to promote the public health. It was the first to show their necessity, and it has been, down to the present time, perseveringly engaged in devising means to prevent the manifestation of disease, or in the skilful application of remedies when it makes its appearance. Scarcely has there been a medical practitioner throughout the kingdom who has refused to give to the appointed officers a correct certificate of the cause of death. Hence the statistics which the Government possesses of the various diseases that have exerted a fatal influence on human life have been furnished, without fee or reward, by the members of the profession. The public now having been so liberally assisted, have only to complete their own salvation, by demanding the immediate removal of those causes of disease which ignorance or error have brought into existence—the closing of all graveyards in the midst of densely populated localities, the proper construction of all drains and sewers, the free admission of the air and light of heaven to their dwellings, and such a supply of water as shall ensure cleanliness both in streets and houses. The Registrar's returns will not then tell of thousands prematurely slaughtered, but far greater numbers than have been hitherto known will arrive at the good old age of three score years and ten, while science will receive an unfading crown for achieving such triumphs.

THE CASE OF DR. WARREN AGAINST THE CORONER OF WEST MIDDLESEX.

We have not space this week to consider the important complaint which the respected surgeon to the 7th Hussars found it necessary to bring against a Middlesex coroner for his conduct to him and the public at the Hounslow inquest. The facts charged are too numerous, too serious, and too extraordinary to be cursorily disposed of; and we propose, therefore, going through the whole case in successive numbers. In our next we shall limit ourselves to three points:—

1. The suppression of the testimony of Lieutenant-Colonel Shirley and Private Rising; the character of that testimony; and the extraordinary circumstances accompanying the suppression.
 2. The private colloquy between the coroner and his deputy, and the two privates, Matthewson and Ellsworth, during the inquest, with the evidence in support of the allegation.
 3. The alleged instructions for a verdict to Mr. Peacock during the proceedings.
- We shall fully consider all these points in our next.

THE MEDICAL TIMES.

We are able to announce that the important course of lectures on Materia Medica, by Dr. Rouppell, the distinguished lecturer of St. Bartholomew's, will be commenced in our next number. We give this prior notice, because we know that our announcement of them excited very general interest, as evidenced by the many queries which have been addressed to us in reference to them, and in the belief that that portion of the profession who are not regular subscribers will avail themselves of this occasion to commence their subscriptions.

THE NATIONAL INSTITUTE.

The deputation from this voluntary incorporation were most courteously received by Sir G. Grey, who paid marked attention to their objections, to which he appeared to attach much weight. We shall notice the details of the interview more at large in our next number.

[To the Editor of the Medical Times.]

"'Tis pleasant, sure, to see one's name in print."—BYRON.

SIR,—Having read an account of a meeting, which was held at the Freemasons' Tavern on the 3rd instant, to petition Parliament in favour of the Registration Bill of Mr. Wakley, allow me, through the assistance of your watchful journal, to state that many of those who attended the said meeting are only anxious for some bill like the one now before Parliament, to enable them to place their names on a Government register, as an easy security (they think) of evading any further examination, or subjecting themselves to any other test (save the diploma of the Royal College of Surgeons), as proof of their medical education, fearing, as many of them do, that the National Institute will require some test of the kind. There will be found among this self-elected committee some who do not possess the Apothecaries' diploma—the only one now-a-days to secure to the public an educated general practitioner.

Some members of the said committee have never opened a classical book—the first step towards a preliminary education, and the sure foundation of sterling medical knowledge.

As to the member of the National Institute, who claimed the privilege of being one, and in favour of the Registration Bill, *how is it that we do not find his name among the members or licentiates of the Apothecaries' Company, though some five or six years in practice as a general practitioner?*

I would urge the committee of the Institute to be alive and stirring; there is, I fear, some under-hand work in the camp.

"Arise, awake, or be for ever fallen."

I am, Sir, your most obedient servant,

VERITAS.

P.S.—You will confer an obligation by allowing this to appear in your next *Medical Times*.

London, May 10.

[To the Editor of the Medical Times.]

SIR,—There appeared in last week's *Medical Times* an account of the death of a young lady at Nice, who had been under the care of Dr. Henry Cecil Gurney, of that place; and, as the most absurd and grossly exaggerated reports of this case have appeared in the French journals and elsewhere, I trust you will allow me a space in the *Medical Times*, to put forward a candid statement of a few facts connected with the same.

The influence which a public journal exercises over the opinions of the public is powerful; it is, moreover, its privilege to expose the folly of the ignorant and to lay bare the artifices of the designing; when then, Sir, the character of an intelligent physician is undeservedly attacked, you will, I make no doubt, feel it your duty, as also will you make it your pleasure, to defend him against unfounded accusations. As the whole case, together with the opinions of the Court Medical, are at this moment in the hands of the printer, I can do little else than give you a brief outline. Should you, however, consider the case of sufficient importance, you can have it for next week's *Medical Times*.

An English physician commences practice on the Continent, and secures to himself a highly-respectable practice; he extends his connection far beyond even his own anticipations; the jealousy of certain persons is excited, and they await an opportunity of ridding themselves of one who stands so much in their way.

A case occurs of a young lady, aged twenty-four, who is taken ill; Dr. Gurney is sent for. She was in very delicate health, and, six months before the time of her present illness, had experienced a severe attack of a disease similar to that which I am about to describe. She was then given over by her medical attendants, but she recovered. Her present symptoms were vomiting of bilious matter, and spasms; her sickness increased in intensity, and became almost incessant; the spasm of the stomach and abdominal muscles became so great that nothing whatever could be retained in the stomach, either fluid or solid, not even the medicine; matters got gradually worse, and she died from exhaustion—collapse. *Post-mortem*

examination discovered a tumour in the gall duct, which was allowed to have caused all the symptoms.

The remedies employed were prussic acid, opium, the warm bath, with brandy and soda-water. These were given in very minute doses, but however, whatever the dose was, she vomited it up immediately. It was stated in the *Medical Times* of last week that the doses were large, and that an acid containing fifteen per cent. of anhydrous acid was used; this is not the case, as an acid containing only one and a half per cent. was employed—a French preparation, made by a resident chemist at Nice, who was with Messrs. Savory and Moore, of Bond-street; the difference between these two strengths is sufficiently great to be remarked. Reports were spread by enemies, and Dr. Gurney was accused of poisoning his unfortunate patient, and arrested; but as soon as any investigation was established, Dr. Gurney was immediately released, and your journal contains Lord Palmerston's letter upon that subject. Dr. Gurney was not satisfied with his acquittal alone, and he determined on sending the case up to London to receive the opinion of higher authorities.

The friends of the family having requested me to obtain this opinion, I laid the case before Dr. Babington, Mr. Bransby Cooper, and Mr. Taylor of Guy's Hospital, to none of whom was Dr. Gurney known; and Dr. Leeson of St. Thomas's Hospital was also consulted.

These gentlemen most unhesitatingly gave it as their opinion, that there was quite sufficient found in the body in the *post-mortem* examination to account for her death; that Dr. Gurney had treated the case most judiciously and scientifically, and that nothing could have been done that would have saved her life. This testimonial is also in the hands of the printer.

A great deal has been said of Dr. Gurney's having left the place in consequence of all this; this is not true, as Dr. Gurney still remains at Nice, in the full confidence of his numerous friends, and is as actively engaged as ever in the practice of his profession.

And of those who sympathize with Dr. Gurney in this unfounded attack on his character, none do so more sincerely than the parents of the young lady whose death he was said to have caused.

I remain, Sir, yours, very obediently,
H. C. BRENCHLEY.

ON SCURVY.

By THOMAS WILLIAMS, Esq., Pwllheli, North Wales.

Scurvy arises from want of fresh vegetables, or their preserved juices, as articles of food. That it should now show itself is not a matter for surprise, considering the great scarcity and high prices of potatoes, greens, &c.

During the last few months a great many cases have come under my notice, and all have occurred in patients above twenty years of age—children, though restricted to the same diet as their parents, being exempt from it.

The patients, if poor, without an exception, when questioned respecting their mode of living, tell the same tale—that they have lived, or, more correctly, subsisted, upon bread and butter, tea and coffee, without potatoes, or any other sort of vegetables, from eight to eighteen months.

The disease is not, however, confined to the very poor classes, but is as frequent in those who eat largely of fresh meat and bread: cold and damp localities favouring its development, in conjunction with the causes above enumerated. It generally begins with soreness of the gums; a feeling of weakness, especially of the legs, about the ham and calves—the knee-joints are swelled, stiff, and painful, and the leg bent and fixed at an obtuse angle with the thigh; subsequently, the lower extremities are observed to be speckled with petechiæ, so general in some cases as to occupy the whole of the thigh, surrounding the knees and calves, often accompanied with œdema of the extremities.

Dr. Budd, in "The Library of Medicine," maintains that scurvy, characterized by fetid breath, fungoid gums, sallow complexion, &c., is not identical with purpura, with which it has often been confounded, and gives valid reasons for coming to that conclusion; and, amongst others, "that the two diseases are met with under totally different circumstances; that they are essentially different, arising from different causes; they differ in the circumstances and mode of attack, and require different remedies. With due deference to the opinion of this distinguished physician, I have seen a good many instances of purpura and scurvy in individuals of the same age and habits, subsisting upon the same kind of food, both presenting essentially the same symptoms, with this exception, that the pathognomonic symptoms of the latter disease were absent, and that the discoloured integuments had a striking resemblance to tanned leather, forming a striking contrast with the black and blue colour observed in ecchymosed parts, under ordinary circumstances; the common integument was invariably found in both varieties, if such they be, glued as it were to the subjacent parts. Both were equally available to treatment, which consisted of antiscorbutic fruits, as lemons, oranges, and vegetables, potatoes and carrots.

QUARTERLY RETURN OF THE HEALTH AND MORTALITY IN 117 DISTRICTS OF ENGLAND.

For the Quarter ending March 31, 1847.
(Published by authority of the Registrar-General.)

STATE OF THE PUBLIC HEALTH IN THE FIRST QUARTER OF THE YEAR 1847.

The quarterly returns are obtained from 117 districts, subdivided into 582 subdistricts. Thirty-six districts are in the metropolis, and the remaining eighty-one comprise, with some agricultural districts, the principal towns and cities of England. The population was 6,612,800 in 1841.

Winter appears to be the season in which it is most natural for men to die. For many years the number of deaths in England has been highest in the winter and lowest in the summer quarter. In the summer quarter of 1846 the reverse was observed, the mortality was greater than it had been in any quarter of the seven preceding years; and in the last winter quarter, ending March 31, 1847, 56,105 persons died in the districts which make the returns: a number greater than has been registered in any corresponding quarter, and 6035 above the corrected average.

The annexed table shows that the mortality was considerably above the average in the winter quarters (ending March 31) of 1810, 1811, 1815, and 1847, and much below the average in the winter quarters of 1839, 1842, 1843, 1844, & 1846.

	1839	1840	1841	1842	1843	1844	1845	1846	1847
Deaths registered in the March quarters of nine years	42,410	46,576	46,967	44,903	43,748	46,136	49,918	43,855	56,105
Deaths which would have been registered if the mortality had been uniform, and the numbers had increased from 1839 at the rate of 1.75 per cent. annually	43,581	44,344	45,120		46,713	47,531	48,362	49,200	50,070
UNHEALTHY SEASONS.									
Difference above the calculated number		2,032	1,447				1,567	6,045	
HEALTHY SEASONS.									
Difference below the calculated number	1,171			1,007	2,965	1,395		3,350	

The temperature was below the average, and the severity of the weather was one cause of the increased mortality. It is, however, worthy of remark, that at Greenwich the temperature was lower in the winter quarter of 1845, when the deaths returned were 49,919, than in the past quarter of 1847, when the deaths were 56,105.

The registrars, in their notes, ascribe the increased mortality generally to inflammations of the lungs and air-tubes, to typhus, and other diseases, and the effects of cold on the aged. The high price of provisions is also mentioned.

GOSSIP OF THE WEEK.

ST. BARTHOLOMEW'S HOSPITAL AND MEDICAL COLLEGE.

The annual distribution of prizes, at the conclusion of the winter session, took place on Wednesday, the 5th inst., in the hall of the hospital, in the presence of his Royal Highness the Duke of Cambridge, the Right Hon. the Lord Mayor, the Duke and Duchess of St. Alban's, the President of the Royal College of Physicians, the President of the Royal College of Surgeons, the Master of the Society of Apothecaries, and a distinguished body of governors and visitors. The President, Alderman Lucas, having taken the chair, Dr. Baly delivered a suitable address, mentioning the success of the arrangements recently made by the governors and the Rev. the Hospitaler for the improvement of the Medical School, and the moral and religious culture of the students, by the formation of the collegiate establishment and the institution of daily service in the church attached to the hospital. The number of students was stated to have greatly increased, and the habits of study and the general conduct of the students to be much improved.

Prizes were then presented, with appropriate observations, to the following gentlemen:—

Wix Prize.—Presented by the President: Joseph Eld, Coventry. Absent from illness.

Bentley Prize.—Presented by his Royal Highness the Duke of Cambridge: Joseph Eld, Coventry.

Surgery.—Presented by his Royal Highness the Duke of Cambridge: 1. C. C. Piper, Guildford; 2. A. D. Dunstan, St. Columb; 3. J. P. Badley, Dudley.

Medicine.—Presented by the President of the College of Physicians: 1. T. Sympton, Lincoln; 2. T. W. Crosse, Norwich, and W. H. Slade, Frome—equal; 3. J. Harvey, Derby.

Anatomy.—Presented by the Right Hon. the Lord Mayor. Senior Class: F. C. Maldon, Worcester, and H. Rogers, London—equal. Junior Class: H. Ludlow.

Physiology.—Presented by Mr. Sheriff Kennard. Senior Class: H. Rogers, London. Junior Class: Harvey Ludlow, Hereford.

Materna Medica.—Presented by the Master of the Society of Apothecaries: 1. G. H. Griffiths; 2. J. B. Sheppard, Oxford.

Chemistry.—Presented by Sir R. H. Inglis: 1. F. Pratt; 2. M. C. Funnell, London, and H. Shillard, London—equal.

Midwifery.—Presented by Mr. J. W. Freshfield: 1. T. W. Aldred, London; 2. A. D. Dunstan, St. Columb.

Practical Midwifery.—Presented by Mr. J. W. Freshfield: J. T. Campton, Exeter.

Botany.—Presented by Dr. Wallich: H. R. Hoskins, London.

Medical Jurisprudence.—Presented by Mr. H. Pownall: 1. Joseph Eld, Coventry; 2. W. J. Waterland, Theobald.

Clinical Surgery.—Presented by the President of the College of Surgeons: J. P. Badley, Dudley.

Collegiate Prize.—Presented by the Rev. J. Russell, D.D.: H. Rogers, London.

The annual general view of the hospital took place on Wednesday; upon which occasion the treasurer, accompanied by the governors,

almoners, and surgeons and other officers of the hospital, made their annual visit of inspection through its wards.

The Treasurer's prizes of £5 each to two sisters, and £2 each to five nurses, of the hospital, for exemplary conduct to the patients during the past year, having been awarded, the governors and friends of the hospital assembled in the hall of the hospital, and sat down to a sumptuous repast. Among the company were his Grace the Duke of St. Alban's; Mr. C. B. Baldwin, M.P.; Dr. Paris, President of the College of Physicians, and the medical officers of the hospital, with Dr. Conolly, the Master of the Apothecaries' Company, &c. &c. The company were afterwards addressed by Dr. Paris (who congratulated the governors and the medical profession on the intention of the Government to oppose the Medical Registration Bill), Mr. Lawrence, Dr. Conolly, and other speakers.

NAVAL APPOINTMENTS.—Surgeons: James Carmichael, M.D., to the Howe; John Davidson, to the Dragon.—Assistant-Surgeons: James Peters and Henry Piers, to the Poitiers; Thomas Kincaid, Frederick Joseph Brown, M.D., and W. B. Duly, to the Howe; Nicholas Littleton, to Greenwich Hospital; J. T. Trousdell, to Plymouth Hospital; John G. Campbell, to the Dragon.

UNIVERSITY COLLEGE.—The students of this college have presented to Dr. John Taylor (on his retirement from the professor's chair of clinical medicine, and the duties of physician to the hospital, in consequence of his ill state of health) a splendid service of plate, consisting of a very elegant teapot, cream-jug, and sugar-basin, with a richly chased salver, bearing the following inscription:—"Presented, with the accompanying service of plate, to John Taylor, M.D., late professor of clinical medicine in University College, London, and physician to University College Hospital, by the former and present students of the college, in testimony of their high estimation of his character as a man, of his real and learning as a professor, and of his distinguished abilities as a physician.—March, 1847." The testimonial was accompanied by an appropriate address, and was acknowledged by a very affectionate letter from the learned Doctor.

APOTHECARIES' HALL.—Gentlemen admitted members May 6:—Richard Scott Boley, John Rogers, Edward John ap Ellis Eyton, William Butler, Henry Chawner, Robert Martin Craven, James Graham Nichol, and George Frederick Burroughs.

MADRAS PRESIDENCY.—Assistant-Surgeon T. S. Bell to be Garrison Surgeon of Fort St. George. Surgeon Kellie to be in the charge of the vaccine depot. Assistant-Surgeon T. C. Jerdon appointed Civil Surgeon of Tellicherry. Assistant-Surgeon M. Rogers appointed Zillah Surgeon at Chingle. Assistant-Surgeons Fitzgerald, Wilson, and Mackenzie, to do duty in the northern division. Assistant-Surgeon C. Barclay to do duty in Malabar and Canara. Assistant Surgeon E. M. Jackson to do duty with the Sappers and Miners at Aden. Assistant-Surgeon W. Forrester to do duty in the centre division. Assistant-Surgeon J. W. Firminger, in the ceded districts. Assistant-Surgeons E. Dixon and C. Kevin are at Madras on leave. Assistant-Surgeon J. Hehen to be Surgeon, vice Desormeaux, deceased. Surgeon A. E. Blest, M.D., has leave to Bombay, and has retired upon a pension of £250 per annum. Surgeon J. Morton has retired upon a pension of £300 per annum. Surgeon J. Cooper to the 4th battalion of Artillery. Surgeon J. Kellie to the 1st European Regiment, Fusiliers. Surgeon E. Smith, to the 2nd Native Veteran Battalion. Assistant-Surgeon G. Smith, M.D., to join the northern division. Superintending-Surgeon G. Macdonnell to the Hyderabad subsidiary force, vice Desormeaux, deceased. Surgeon J. G. Coleman to be Superintending-Surgeon, ceded districts, vice Macdonnell. Assistant-Surgeons H. Goodall and J. Forbes to be Surgeons, vice Morton and Blest.

retired. Superintending-Surgeon Coleman has retired on a pension of £800 per annum. Surgeon J. Innes has sick furlough to the Cape. Assistant-Surgeons J. E. Mayer and W. Lloyd have leave to Europe, on medical certificate. Surgeon D. S. Young to the 17th Native Infantry. Surgeon W. H. Smith to the 23rd Native Infantry. Surgeon G. Pearse to the 30th Native Infantry. Surgeon De B. Blich to the 12th Native Infantry. Surgeon J. Hichens to the 27th Native Infantry. Surgeon H. Goodall to the 19th Native Infantry. Surgeon J. Forbes to the 38th Native Infantry. Assistant-Surgeon Morton to the 18th Native Infantry. Surgeon A. H. Mahley to the 9th Native Infantry. Assistant-Surgeon W. Kirkwood to the 16th Native Infantry. Assistant-Surgeon H. Smith to the 20th Native Infantry. Assistant-Surgeon A. H. Howe to 46th Native Infantry.

BOMBAY PRESIDENCY.—Assistant-Surgeon G. M. Ogilvie has a furlough to Europe for three years on medical certificate. Assistant-Surgeon McAlister is attached to the 23rd Regiment Native Light Infantry at Bombay. Assistant-Surgeon J. H. Wilnot, ordered on duty to Bombay. Assistant-Surgeons A. R. Fraser, C. C. Mead, and E. De Crespigny, ordered for duty in Scinde. Surgeon P. W. Harkin removed to the 11th Regiment Native Infantry, at Kolapore. Surgeon W. B. Harrington, posted to the 9th Regiment Native Infantry, at Tanmah. Assistant-Surgeon J. Vaughan has passed a vernacular examination. Surgeon B. A. H. Nicholson is on sick leave at Bombay. Assistant-Surgeon Stocks has been appointed a vaccinator in Scinde. Assistant-Surgeon R. Miller is sick at Bombay. Assistant-Surgeon R. Nuttall is on duty at Salsette. Assistant-Surgeon Maitland has passed a colloquial examination. Assistant-Surgeon R. C. Coles to be Assistant Garrison Surgeon at Bombay, vice Ogilvie. Assistant-Surgeon D. A. Carnegie to act as Civil Surgeon at Bombay.

BENGAL PRESIDENCY.—Assistant-Surgeon J. G. Kemp, M.D., is with the 66th Regiment Native Infantry at Dinapore, and posted to the second troop first brigade of Artillery at Hoosheyapore. Assistant-Surgeon W. A. Green, to be Surgeon, vice Lees, retired. Assistant-Surgeon A. Reed has returned from furlough, and been posted to the 46th Regiment Native Infantry, at Jullundur. Veterinary Surgeon J. Booth is with the 9th Light Cavalry, at Cawnpore. Veterinary Surgeon J. Ford has a furlough to Europe on private affairs. Surgeon W. Gordon, M.D., has leave to Calcutta, preparatory to applying for furlough to Europe on private affairs. Assistant-Surgeon J. Harrison, M.D., appointed to the 3rd Regiment Irregular Cavalry at Saharunpore, vice Handyside, promoted. Assistant-Surgeon G. P. Thomson, M.D., transferred to the 2nd troop 3rd brigade, at Ferozepore, vice Harrison. Assistant-Surgeon R. W. Macaulay, M.D., posted to the 1st troop 2nd brigade Horse Artillery, at Meerut, vice Thomson. Assistant-Surgeon C. D. Davidson has passed a vernacular examination. Assistant-Surgeon J. C. Smith to be Civil Assistant-Surgeon to the Salt Agent at Poorie. Surgeon G. G. Brown, M.D., appointed to the Artillery division, at Lahore. Surgeon H. J. Thornton, posted to the 13th Regiment Native Infantry, at Cawnpore. Assistant-Surgeon T. Stott, posted to the 53rd Regiment Native Infantry, at Cawnpore. Veterinary Surgeon J. Booth, posted to the 7th Regiment Light Cavalry, at Muttra. Assistant-Surgeon S. Winbolt has leave to Landour a Calcutta for seven months, preparatory to applying for permission to retire from the service.

A deputation, consisting of Mr. Lawrence, President of the Royal College of Surgeons in England, and Messrs. Travers and Stanley, Vice-Presidents of the College, had an interview on Saturday with Sir George Grey.

A deputation, consisting of Mr. Ridout, Master of the Society of Apothecaries; Messrs. Bea and Callander, Wardens of the Society; Mr. Baco, Deputy Master of the Society; and Mr. Upton, the Clerk to the Society, had an inter-

view with Sir George Grey on Saturday, at the Home-office.

Dr. Paris, President of the Royal College of Physicians, Dr. Burrows (Senior Censor), Dr. Budd (Censor), Dr. Francis Hawkins (Registrar of the College), and Dr. Nairne, had an interview with Sir George Grey on Saturday.

Mr. Macdon has sent us samples of his extract of opium. Glad at all times to recognize the improvements introduced by our scientific pharmacologists, we have given it the trial he has invited from us, and are enabled to pronounce it a very superior preparation.

HASTY INTERMENT.—The French journals abound in instances of a too hasty interment after apparent death. *Le Rhone*, a provincial journal, announces a case of hasty burial at Clurey. A stonecutter had been buried alive, and the sound of the earth, as he fell on his coffin, awoke him from his lethargic sleep. The impression produced by this event was so great as to overturn the reason of the sufferer, who, animated by a supernatural strength, burst open the coffin lid and fled from the cemetery. He was overtaken only with great difficulty, after having been pursued a considerable distance. The *Journal de Bordeaux* announces a similar occurrence a few days before the above. The wife of a rich farmer of Laurae, after a short illness and apparent death, had been buried with the accustomed formality. A few hours after the sexton, passing through the graveyard, imagined he heard groans coming from under the earth. He hastened to inform the curate, who ordered the grave to be opened. The woman gave signs of life, but did not recover her consciousness, and owing to the brutality or the superstition of the neighbouring inhabitants, who refused to have her admitted into their houses, she perished before medical assistance could be rendered.

OBITUARY.—On Wednesday, the 5th inst., of No. 2, Circus, Bath, Stewart Crawford, Esq., J.D.—On the 1th inst., J. P. Simon, M.D., formerly of Dublin, at 5, Tavistock-row, Covent-garden, aged 52.

Magneto-Electricity in Narcotic Poisoning.—A gentleman swallowed what he purchased as half an ounce of powder of cubeb. He retired to rest, but almost immediately felt a dizziness, with inclination to sleep. He was not discovered till the next day at twelve o'clock, when he had the most urgent symptoms of narcotic poisoning. Emetics of sulphate of zinc, mustard and water, were employed, the feet immersed in a bath of mustard and water almost to boiling. The patient appeared, notwithstanding, to be fast sinking, and, though remedies were perseveringly employed, nothing seemed capable of arousing him. At this juncture Dr. Page resolved to try the effects of magneto-electricity. While an assistant rapidly rotated the wheel, the balls were applied at first to each side of the neck, and then down behind the clavicles. This produced convulsive movements of the arms and body, without consciousness. On applying a ball over the region of the heart, and one to a corresponding point on the right side, the eyes opened widely in an instant, the head and body moved convulsively, and, after three or four applications, reaction was so positively established that there was no further use for the machine. On the following morning the patient was pretty well.

Spontaneous Evolution.—Dr. Simpson observes—1st. That spontaneous evolution in transverse presentations was not so rare as some authors averred, and that it would probably occur oftener if proper and timely assistance were not rendered. 2nd. That, under some circumstances, arm and shoulder cases should probably be left to be expelled by the mechanism of spontaneous evolution, assisting, if necessary, this mechanism by art. 3rd. That this ought to be our practice, if, in an arm or shoulder case, the chest or trunk of the child be already thrust down into the cavity of the pelvis; for to turn under such a complication, and, with that object, attempt to push back the body of the child from the cavity

of the pelvis into the cavity of the contracted uterus, would necessitate the redilatation of the uterus, and hence, in all probability, produce a rupture of its coats. 4th. That if the process of spontaneous evolution failed, two operations had been recommended to effect delivery, viz., evisceration and decapitation; and they had always been described as applicable to the same set of cases; but they were, in reality, individually applicable in two different sets. 5th. That evisceration was only applicable to cases of pelvic spontaneous evolution, demanding operative interference; and decapitation only applicable to cases of cephalic spontaneous evolution. 6th. Of course in all common transverse presentations seen before the body and bulk of the infant was doubled and thrust down into the cavity of the pelvis, and was still, in fact, in the cavity of the uterus, turning was the proper practice, and to wait for the prospect of spontaneous evolution would be utterly wrong. And, 7th, a child of the common size could never, in a transverse presentation, be forced and doubled down into the cavity of the pelvis, unless the pelvis were large in its dimensions, and hence, when the process of spontaneous evolution is found in an advanced stage, it is almost a certain sign that the pelvis is of such measurements as to give a chance of its completion.

Analysis of the Blood after Inhalation of Ether.—M. Lassaigue, from experiments, has found that blood taken before and after inhalation did not differ sensibly in colour, nor as to coagulation; afterwards it exhaled a strong odour of ether. The serum and clot in two specimens differed as follows:—

Before inhaling	{ Clot ..	65.46
	{ Serum ..	34.54
		100.00
After ditto	{ Clot ..	59.69
	{ Serum ..	40.31
		100.00

After inhalation the serum acquires a slight reddish tinge; the clot appears less consistent before than after; the globules, fibrine, and albumen preserve the same proportions after as before; the quantity of ether absorbed about 1/1000th of the quantity of the venous blood.

MORTALITY TABLE.

For the Week ending Saturday, May 8, 1847.

Causes of Death.	Total.	Average of 5 Winters.
ALL CAUSES.....	987	914
SPECIFIED CAUSES...	985	909
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	137	166
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat.....	113	109
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	167	158
Diseases of the Lungs, and of the other Organs of Respiration.....	314	275
Diseases of the Heart and Blood-vessels.....	45	29
Diseases of the Stomach, Liver, and other organs of Digestion.....	91	70
Diseases of the Kidneys, &c.	12	8
Childbirth, Diseases of the Uterus, &c.	22	10
Rheumatism, Diseases of the Bones, Joints, &c.	12	
Diseases of the Skin, Cellular Tissue, &c.	4	2
Old Age.....	54	57
Violence, Privation, Cold, and Intemperance....	14	28

No. 399.

COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the THEATRE of QUEEN'S COLLEGE, Birmingham.

By SAMUEL WRIGHT, M.D.,

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Cuvierian Natural History Societies of Edinburgh, &c.

Feigned and imaginary diseases; importance of knowing them; difficulty of discovering and treating them; most common amongst females; probable reason of this; reflections upon it; sometimes met with in men; explanation of the division, feigned and imaginary; case of the former in full detail, and comments upon it; another case somewhat similar; circumstances under which description of this kind is generally practised; exceptions to the rule; illustration; various motives to the feigning of illness; examples; various assumptions of disease, particularly that of diabetes; detection of this imposture; applications to physicians for certificates of ill health after their refusal by surgeons; cautions respecting the giving of these; further illustrations of feigned disease; imaginary diseases; examples.

GENTLEMEN,—I will take the present occasion to offer a few observations upon the subject of feigned and imaginary diseases. This subject you will hereafter find of not trifling significance, for it will meet with many illustrations in your career of practice. *Realities*, in the shape of troublesome or intractable ailments, are what you will chiefly have, professionally, to contend with; but *idealities*, and of these not a few, will frequently come before you for correction. You will find them not very easy of management of mastery. The morbid fears and fancies of patients are strange besetments, and the ingenuity and judgment of the practitioner are often severely taxed in treating them. For detection and defeat, they require a nicety of discrimination, and great decision of purpose, on the part of the medical man: to err in diagnosis, or to waver in determination, in such cases, is sometimes to incur the risk of personal ridicule—it has even incurred the more serious risk of professional ruin. These are grave reasons, then, why the subject should be brought before you in the shape of a clinical discourse; it becomes your teachers to make you acquainted with it—by none other means can you learn it so easily or so well as by practical illustration.

Examples of the subject I am alluding to are usually met with amongst females, especially of the delicate, sensitive, hysterical, and idle classes. Women, as a rule, have minds less vigorous and thoughtful than those of men; their reflective faculties are less developed; to use a plain simile, they carry more intellectual stuff than ballast, and are therefore more easily affected by casual circumstances. Hence their tendency to fears and fancies; and hence the

necessity, in treating these, to ever bear in mind the fact, that they have their origin in weakness, and to let the firmness of your discipline be tempered with that politeness and delicacy which are constantly due from our own sex to the other.

Sometimes the peculiarities in question are found amongst men—amongst those sighing, sentimental, languishing somebodies—a sort of breeched Mrs. Wittnerlies—who are a libel upon the sex whose name they carry. For myself, I must confess that bare civility to subjects like these is as great in act of favour as my charitable feeling enables me to offer.

The division which I have made of these ailments is into *feigned* and *imaginary*: the former are assumed for some deceptive purpose or other; the latter exist only in the patient's disordered imagination; these are much more common than these, and happily, also, are much more easily curable.

The first case I will call your attention to is that of Harriett —, known, I believe, pretty well to all of you, for she has scarcely ever been off the hospital books since they were first opened. She boasts the acquaintance of nearly all the leading professional men in the town, who have variously but vainly essayed her cure—for charity's sake! I had not been attached to the hospital a fortnight, before she procured a home-patient's ticket, and desired my attendance, as she lived in my district. Knowing well her history, and suspecting her scheme, I did not visit her immediately, as I had been requested, but put her upon my list for the following day. In the morning, however, another messenger came, with the admonition that, if she were not directly seen and succoured, it was doubtful how much longer her valuable life might last. Of course I posted off instantly, fearing that she might possibly be really ill. I arrived in time to see her go through the finishing scene of a most substantial repast, in the business of which I curiously avoided interrupting her, for it was quite a treat to see an excellent appetite so generously supplied. After having appropriated the eatables, she disposed, at a draught, of a fair quantity of ale, and then proceeded to tell me how very ill she was. I had more than once before heard her tale of personal troubles, when calling to see her as a curiosity, with different professional friends who were at times in attendance upon her; but, as though hearing it for the first time, I sat most attentively while she

went over the old story of aches, and pains, and palpitations, and sickness, and sleeplessness, and the many other items that constitute the protean infirmities of those who have inwardly resolved never to be well. She further entertained me by going back to the commencement of her illness, when she was fifteen years of age, which is about five-and-twenty years ago, and enumerating the different attacks she had had between that time and the present. She vowed that she had suffered from gall-stones, stone in the bladder (one physician, I know, gave her up as incurable, when she showed him a quartz pebble, which she declared she had passed *per urethram*), tumour of the liver and of the uterus, heart disease, spinal affection, frequent cough, and constant indigestion. The time I spent in hearing this absurdity was really not wasted, for the suggestiveness of the woman was quite a study. She lives but little more than a stone's throw off the hospital, so I inquired if she could not make it convenient to come to me there as an out-patient? She assured me this was impossible, as she caught cold directly she went out of doors, and to walk the length of the street was martyrdom to her. The gentleman from whom she obtained her ticket lives about two miles from her: I asked if she went for it herself? She said yes, and walked both ways, but "found herself very much done over, as it rained very hard, and the ground was deeply covered with melting snow." After further inquiry and examination, I plainly told her that I thought she had swallowed physic enough, and had better see how long she could contrive to live without it. This suggestion she met with a distinct denial of the possibility of her lasting much longer, unless medical aid were constantly afforded. I was then obliged to assure her that I had no doubt whatever about her case, and that I did not intend her to waste my time, or the hospital's drugs. Judging from my manner that imposition would not be very practicable, nor the process of it very pleasant, she wished to know if I could not turn her over to the surgeon of the district. She had been under his care two or three times. I told her that my intention was to send the note back to its donor, with an assurance from me that he might easily find other objects more deserving of it than herself. Of course she was very indignant, but that was of no consequence.

In this woman's case I suspect there are two causes which will account for her love of being

constantly on the sick-list. She is somewhat fat, and obviously very idle. She shares, or rather ought to share, with her mother, in the management of an infant school. Now, the duties of this are somewhat more irksome than she likes, and she therefore contrives to throw the greater part of the weight on her parent's shoulders, by assuming herself to be too delicate to encounter it. To be constantly complaining of inability to work might lead to suspicion, were not some of the unities of indisposition perpetually presenting themselves. These she supplies in all sorts of affected pains, in periodical doctor's visits, and in the disposal of as many pills and potions as may be sent to her. There may be another motive than this: she may love, and I think she does, to be considered an invalid, and to be honoured in the constant attendance of a medical man, even though he receive no remuneration for his trouble. The feeling may lie deeper, and be less delicate. One of her attendants applied the *spectrum uteri*. She fancied she had disease of the uterus ever after! Whatever might be the cause, there was no doubt of the imposition, or attempt at it; and it was a duty I owed, as well to the hospital as to myself, to prevent the imposition.

Some time ago I had a patient—a fanciful young girl of sixteen years of age—whose parents were too poor to feed and clothe her after the fashion she desired, and herself was too idle to help them in any way. After affecting various ailments to no purpose, she persuaded her mother that there must be a communication between her bowels and her bladder; having eaten plentifully of cherry-pudding one day, and swallowed most of the stones, she afterwards showed these to her credulous parent, declaring that they had passed *per urethram*. The poor old woman came to me in an agony with them, and imploringly asked what could be done? My advice was, that she should for the future pay no attention to her daughter's ailments, but lock up her fine clothes and keep her on low diet until she recovered. It was not long before I learned that the suggestion had been perfectly successful.

You will generally find that deception is chiefly attempted to be practised upon you by those who solicit your gratuitous aid. The physis costing them but little, and the advice costing them less, they are scarcely encumbered by their efforts of artifice. Again, people of this class are usually those upon whom the benefits of education have operated but sparingly, and they are consequently unguided and uncontrolled by moral causes that upon others, better trained, have a stronger influence. There are exceptions, however, to this rule. Many an alliance, honourable and dishonourable, even in respectable families, has been formed over a bed of assumed sickness. During my apprenticeship a joke was rife in the town, concerning a lady of some intellectual and family pretensions, who betook herself to bed for a whole twelvemonth, and for no obvious reason other than that of encouraging the visits of a quack doctor, who, amongst other delicate stories with which he was wont to amuse his patients, used to relate the execrable adventure of having stolen a dead body from the spot sacred to its burial.

Illness is sometimes feigned by the indigent in the hope of making it a source of improved subsistence. In connection with the General Dispensary, we have a fund which enables us to provide the necessaries of life for those of our patients who may happen to be destitute of them. Excellent as this privilege is, there is often required some circumspection to prevent the abuse of it. I have frequently found my patients obtaining a renewal of their notes, not because they wanted much physic, as they said, but because the tickets for meat and bread were so very acceptable. One old Irishwoman in particular completely exhausted my patience, and I suppose also the recommendations of her friends. I lost sight of her at the dispensary for several weeks. One morning, however, she made her appearance, as an out-patient at the hospital. There was nothing amiss with her

worth a mention; but you remember her asking me if I could bestow a few relief tickets upon her, at the same time assuring me of her ardent love for me, and her profound regard for the boundless benevolence which she was sure I possessed. She was vastly astonished when I told her we did not keep relief tickets; and her estimate of my prescription and her need of it were pretty well shown in the fact that she never came near the hospital again.

Men who are out of employ, and belong to sick societies, frequently feign illness for the sake of obtaining relief from the "box." The tricks resorted to in these cases are sometimes very ingenious, and require some sagacity to detect them. Those who happen to have learned the deceptive art in the army are exceedingly difficult to unmask. They can produce superficial inflammation, swelling, or eruption, at pleasure; establish a slough which no human ingenuity can heal, until they choose to let it; go into fits that look as natural as though they could not be helped; be paralyzed all over, or in part, for any length of time they like; vomit as if they cirrus of the pylorus; cough as if they were consumptive; purge like cholera; and urinate like diabetes. This last is an old trick, and was often a very successful one when the only diagnostic process consisted in tasting or fermenting the secretion. If the patient clandestinely added sugar to it, of course its taste would be proportionately saccharine, and carbonic acid, corresponding to the quantity of sugar present, would be produced by fermentation. The potash or milk of lime test, however, enables us to detect the imposture: for it is with *grape*, not *cane*, *sugar* that they produce the characteristic brown colour on boiling.

Impostors of the class I am now mentioning, if detected and exposed by their club surgeon, often seek to retaliate upon him by applying to a physician for gratuitous advice, and persuading him to certify to their indisposition and unfitness for labour. In this manner they bid fair to disturb the harmony, good feeling, and good fellowship, which should ever extend themselves between one professional man and another. This is one of the many things which often interfere with the right continuance of brotherly regard amongst us. The general practitioner feels, and very properly, that his opinion, perhaps the result of long and cautious observation, has been unjustly set aside by a certificate given by a physician, after a single and, perhaps, only a short interview with the patient. It may have been, and most likely, that the physician intended no wrong; but in cases like these there is nothing like caution. Let me advise those of you who hereafter intend to practise medicine exclusively to be mindful how you act under such circumstances. Certificate, like testimonial, giving ought to be considered a serious thing. If a case like that I have mentioned come before you, advise the man to go to his surgeon for the warranty—depend upon it, his regular medical man will be the best judge. If this do not answer, see the surgeon yourself, and determine together what may be best to be done. To do this, will be to save yourselves and others frequent unpleasantness.

Imposition of the kind I am speaking of is frequently met with amongst the in-patients of hospitals. In the course of my professional lifetime I have met with many examples of it, and yourselves have lately seen not a few in the Queen's Hospital here. At one time, as I have before told you, there were no less than five girls, all under my care in one ward, who were attempting to practise deception. The first that I dismissed burst into tears on being told that she must go, and assured us that there was no home to receive her. This was a painful thing to hear; but, with the hospital quite full, and urgent cases refused daily for want of room, it was quite out of the question to keep those who were bodily well, merely because they had no settled place of residence. On the day of this girl's departure, I requested her to call upon me, as an out-patient, in three days. She did so, comely enough

dressed, and I then found that she was staying with an aunt, who was glad to find her shelter when she discovered that the hospital would keep her no longer. An Irishwoman, you remember, I dismissed about three weeks ago, who abused the nurse right well before the committee, as the cause of her ejection. I was satisfied of her cheat for a week before I parted with her. She gravely told me she had no means of getting a bit of bread, unless she got employment; and I replied, that I thought that was the case with most of us. Stout, hearty, and an excellent eater, she begged emphatically for another week's idleness; but, finding entreaties unavailing, she coolly packed up for departure, leaving a polite benediction for the nurse as she went away. Another girl, Unwin, in the same ward, I had some difficulty in dismissing. She liked her residence so well that there seemed some improbability as to the time when she might take a fancy to leave it. When a necessity for her departure was hinted, she referred the authorities to her father, who could command tickets, she said, to keep her in as long as he might choose. The father, hearing this, demanded an audience of me, and, not being at the hospital at the time, the nurse referred him to my house. He came accordingly, wishing to know, why his daughter was to be discharged? I answered, interrogatively, why did he wish her to be kept in? I told him she had a good pulse, a clean tongue, a bright eye, a clear complexion, an excellent appetite, and, as he could testify, she was not wanting in strength, for most days she walked three miles in paying a visit to her paternal residence. He then plainly told me that he could not maintain her, and could not induce her to work, and had sent her into the hospital as a last chance. I suggested to him that the hospital was not a workhouse, and that he ought not to attempt to abuse its charity. I gave him further advice about managing his intractable representative, which I hope would have the effect of curing her of idleness and schemes of imposition.

In all cases of this kind, once fully detected, firmness should be your principle of treatment. It may be that there are inducements to lead you to yield to the artifices of the tricksters; but it will mostly be that there are higher motives than these, directing you another way: let the latter guide you. Always merge lesser considerations into larger ones—do what a conscientious judgment tells you is your duty, and you will do right!

Upon the subject of imaginary diseases I have little to say; if I said more, I must of necessity say a great deal. Whole books, you know, have been written upon this most prolific theme; and no doubt whole books have yet to appear on the same subject. These ailments are generally difficult of cure—often they defy it. My business, however, is not with those cases that depend upon a constitutionally-disordered mind; or upon other causes than general weakness, or sympathy between the brain and some remote suffering organ. General nervous debility has a great tendency, in certain people, to show itself in some hallucination or other. If in the person of a girl, she may become merely hysterical, or fancy some of the ten thousand absurdities that attach to the weaker sex at a delicate age; if in a boy in his teens, he will fall in love, fancy himself a man, and despise the authority of his master—his *ultimatum* is the stage, or the sea, or, if strong enough, he may fancy the army; if in the person of a married woman, according to the circumstances of her domestic treatment, will she be liable to weep over her husband and children, and quietly take to drinking, or to rave about the infidelity of her inferior half, and vow, if it were not for the little ones, she would drown or poison herself; if in the person of a married man, he fancies himself overwhelmed with debt, forges his family in ruin, and, by way of helping them thereto, absconds from them, or makes the public-house his home, or cuts his throat.

It has often occurred to me to think, and often

indeed to know, that many of the acts of people, which in our cool calculating moments we are disposed to judge harshly of, really deserve our pity, from the artificial circumstances which have suggested them. I am inclined to believe that rational man is not generally disposed to belie his nature; but there are certain occasions when he rather rejoices in doing it. Depend upon it, if there be no radical mental defect, these occasions are when some of his more important animal processes are going wrong. Of these, none are more influential than the functions of the stomach and liver, and (in the female) uterus. Fairly derange these, and it will be a wonder if the brain have not some participation in their error. Wrong ideas and weak judgment are amongst the most common symptoms of amenorrhœa. You remember a case of this kind we had some six months ago: all the hallucination vanished directly that the catamenia appeared. The man in the middle ward, whose dusky complexion and clayey stools I directed your attention to a few weeks ago (I forget his name at this moment), had extraordinary dreams when asleep, and still more extraordinary imaginings when awake, as you will recollect. I was half afraid, at one time, that his brain was something more than disordered sympathetically with his liver. All these extravagancies, however, left him directly that the biliary secretion became restored, and passed off by the bowels. The out-patient, with the pale face, sunken cheeks, and hollow eyes, whose case I particularly adverted to last Wednesday, is the subject of general nervous debility; but this is chiefly shown in his gastric functions. With the state of his stomach his brain sympathizes, and the poor imbecile creature is barely fit for the common purposes of life. He has improved somewhat under stimulating and tonic treatment, but still his fears and fancies are of a painful and most pitiful nature. Mrs. Frost, who is still in the hospital, we thought, from her strange wildness and incoherency, added to other indications, was the subject of brain disease when she first came in. I am now inclined to think that all her anomalies arose, primitively, from the condition of her stomach. At least she has gradually but substantially improved, under the use of regular purgatives, tonics, and diffusible stimulants. You remember how the calomel purge, followed by generous diet, wine, and ammonia, quieted the turbulent brain of the poor woman in the top ward, three months ago, who fancied she was possessed of the devil.

I could dwell upon many such cases did our time permit; but I have not space for detail. In treating patients of this class, considerable discrimination and tact are generally required. Your first object, of course, is to find out, if possible, the origin of the malady. If it appear to you, on examination and deliberate reflection, that the patient is only fit for an asylum, lose no time in sending him thither. But be cautious how you come to this conclusion: much may hang upon it.

If remedial treatment, within your own scope, be wanted, administer it without harshness or severity. People whose fancies are morbid are on no subject more so than on that of personal kindness or cruelty.

If their passions are roused, soothe them; if their spirits are depressed, cheer and sustain them. It may be that moral causes, only recent, are in play, which "a word spoken in due season" may go far to rectify.

If you can trace the derangement to organic causes, capable of rectification, proceed unhesitatingly in your work of improvement until you have completed it.

MUCH CRY AND LITTLE WOOL.—We see by the Parliamentary return, that, though fifty-five petitions have presented for the Registration Bill, they possessed but 147 signatures—less than three each! For the new bill of the druggists there have been thirty-four petitions, with 462 signatures.

A COURSE OF LECTURES ON SURGERY,

BY
SAMUEL COOPER, Esq., F.R.S.

Professor of Surgery to University College, London;
Consulting Surgeon to London University Hospital, &c.

LECTURE VI.

At the conclusion of the last lecture, gentlemen, I entered on the consideration of the causes of inflammation; and I mentioned excesses in diet, accompanied by indolence, and especially the propensity for stimulating drinks, as calculated to produce a strong disposition to inflammatory affections. Such habits not only predispose to inflammation, but they also induce a peculiar state of the system which renders the party unable to bear up against its ravages. Such persons are, indeed, bad subjects for all kinds of disease, and they usually succumb to it in a very short time. Operations are more frequently fatal to such persons, unless they are previously prepared for them by antiphlogistic measures—such as bleeding, low diet, and a proper regimen. Unless such preparatory treatment be enforced, operations are very commonly unsuccessful. Unfortunately, it is not always possible to submit the patient to this preparatory regimen, as in cases where accident, such as compound fracture, demand immediate amputation, and the limbs are so shattered as to leave amputation as the only chance for saving life. Sedentary, studious habits, accompanied by indulgence in the luxuries of the table, always induce a tendency to inflammation, and sometimes produce the gouty diathesis, or call it into action where there is already an hereditary predisposition. We should always bear in mind, among the predisposing causes of inflammation, peculiarities of constitution, or idiosyncrasies, because these explain to us why some individuals are the subjects of gout, others of rheumatism, and others, again, of scrofulous inflammation; although all may be living in nearly the same manner, and indulging in the same habits.

We now arrive, gentlemen, at the exciting causes of inflammation, among which I may enumerate mechanical injuries of different kinds—wounds, fractures, sprains, bruises, friction, pressure, or irritation caused by extraneous bodies lodged in the body, such as bullets, splinters of wood, fragments of glass, and a variety of other substances. Stimulating applications and other matters which exercise a chemical action on the texture of the part may be mentioned as exciting causes, by far the most frequent of which are caustics, fire, and heated substances. Among the most common of the exciting causes, is the application of cold, which sometimes acts directly on the part, as in frost-bites, inflammations of the larynx, trachea, or lungs, excited by the entrance of cold air; at others indirectly, as when the action of cold on the skin suddenly suppresses the cutaneous transpiration, and produces fever and inflammation of some part not exposed to the direct influence of cold. The locality in which inflammation excited indirectly by cold shows itself is different in different persons. Thus, the application of cold to the feet will cause inflammation of the lungs in one person, sore throat in another, inflammation of the bowels in a third, and shall produce no injurious influence on a fourth. In all these cases cold must act as an indirect rather than a direct exciting cause of the disease. The sudden warming of a part which has been long exposed to cold generally produces a violent inflammation which is checked and controlled with great difficulty; and here again cold acts in an indirect manner. Chilblains are instances of the action of cold in exciting inflammation, but it is by no means uncommon to see a part or the whole of a limb destroyed by mortification resulting from the in-

flammation induced by cold. The sudden application of heat, or rather the sudden change of temperature, is here the true exciting cause of the inflammation, which may be avoided by a slow restoration of the natural heat of the part. Inflammation, again, may be produced by the sympathy of the part attacked by inflammation with some other part to which the causes of irritation are applied. Particular kinds of food and medicine introduced into the stomach may produce peculiar inflammation of the skin. In some states of the system mercury produces an inflammatory redness of the skin which is called mercurial erythema, and nettle-rash sometimes follows the eating of shellfish. Abscesses in remote parts of the body are sometimes the result of injuries of very distant parts. Mr. Rose gives examples of death from such abscesses resulting from gun-shot wounds, although the patients had recovered from the direct injury. These remote or sympathetic abscesses are frequently seen in the lungs, the liver, the pericardium, and serous membranes, but they may take place in other tissues. Injuries of the head were observed by Bertrandi to be occasionally followed by abscess of the liver. Similar deposits of pus in different parts have been not uncommonly noticed as results of phlebitis. These abscesses are now referred to the absorption of pus or some other injurious matters into the system, which, circulating with the blood, excite inflammation, which is followed by abscess, and not to the sympathy of older authors. Among the predisposing causes of inflammation we must reckon fevers. Patients often recover from these, but are afterwards tormented by the inflammations and abscesses which occur as *sequela*. But abscesses are frequently formed during the course of the fever, as in plague; and, as the older practitioners often observed that the patients recovered rapidly after the evacuation of the abscess, they called them critical abscesses. I now, gentlemen, arrive at the most difficult and uncertain part of this subject—the consideration of the proximate causes of inflammation, or, in reality, the nature of the disease. The nature of inflammation, I may venture to say, has puzzled all physicians and surgeons, from the earliest period of the study of medicine to the present day, and will probably remain in a great measure inscrutable to future generations. The proximate cause of inflammation may be said to be that on which the characteristic and essential phenomena of the disease depend—that peculiar action or change which, commencing with the commencement of inflammation, accompanies it through all its stages. It is, therefore, the essence or nature of the disease itself. Many and various have been the opinions formed to account for the phenomena of the disease. The older physicians, and the celebrated Boerhaave among the number, following the humoral pathology, indicated a lentor or visciditas of the blood as the immediate cause, supposing at the same time that the globules took a wrong course, and were forced into vessels not intended to contain them. Even were these circumstances proved to be true, they could not constitute the proximate cause of inflammation, and could only be considered as the predisposing or exciting causes. No change in the condition of the blood must be looked upon as the proximate cause of inflammation, whatever effect it may have on the phenomena of the disease: for, if inflammation essentially depended on the altered condition of the whole mass of the blood, the whole of the body should be inflamed; but this is not the case, for the inflammation is restricted to some particular part. There can be no doubt that more blood is sent to inflamed parts than natural, and this, I believe, is universally admitted. You will observe that a much more copious flow of blood follows an incision of an inflamed than a similar incision of a healthy part. Such an increased hemorrhage cannot be attributed to the action of the heart, because this organ propels the blood equally to all parts; but must depend on increase in the

diameter of the vessels leading to the inflamed part, or to some new power of propelling a larger quantity of blood to the inflamed parts in which they are distributed. That an increased determination of blood to parts affected with inflammation exists, is shown by many circumstances in addition to those I have already cited. It is observed in amputation of the thigh, for disease of the knee-joint where inflammation and large abscesses have previously existed, and also in cases where the limb is removed in consequence of had compound fractures accompanied by severe inflammation and profuse suppuration, that the flow of blood is much greater than under ordinary circumstances, and that the number of vessels that require ligation is much increased. In such cases many of the small vessels are greatly increased in size.

The phenomena of inflammation, by which I wish to be understood the increased heat and redness; the effusion of coagulable lymph within the texture or on its surface; the swelling and suppuration, are produced by the altered condition of the capillary vessels of the part. The diameter of their canals is increased, so that they are capable of admitting a larger number of red globules than in their natural state. Thus, in the inflammation of the tendons, of which I showed you an injected specimen in a former lecture, numerous red vessels were visible which would not have been seen in a similar injected preparation of a sound tendon. But the question may now be asked, is not something more than dilatation and turgescence of the vessels implied in the action by which the redness, heat, swelling, and pain of inflammation are produced? We are not to suppose that these vessels undergo alternate contractions and dilatations, for we can see with the naked eye sufficient to prove that the phenomena may be the result of dilatation alone; nor are we to suppose that there is constantly increased velocity in the circulation through the capillaries, for we have evidence from the experiments of Drs. Thompson, Wilson, and Hastings, to show that there is diminution of velocity in the capillary circulation as soon as inflammation is set up. In these experiments some stimulants were found to increase the velocity of the circulation in the minute vessels, while others retarded it. The opinion of Dr. Wilson Phillip was, that the proximate cause of inflammation is a debilitated state of the capillaries conjoined with an increased action of the arteries leading to them. We may safely say, then, that in inflammation the velocity of the capillary circulation is not always increased, and, if we can place full reliance on microscopical observation, it should generally, if not invariably, be diminished. We must not suppose that determination of blood to a particular part alone constitutes the proximate cause of inflammation, for such determinations of blood to particular organs are sometimes perfectly natural, and do not induce it; as in animals who copulate at a particular season, the spermatic arteries are found much enlarged, and then there is an increased determination of blood to the organs of generation. The carotid arteries of the stag are much enlarged during the growth of the horns, yet no inflammation is produced. When there is merely an increased flow of blood dilating the vessels, congestion may be said to exist; and this is often a predisposing cause of inflammation, but does not constitute the disease. We may safely conclude that inflammation is accompanied by a greater determination of blood to the affected parts; that the diameter of the vessels leading to the part is increased; and that the blood does not always pass with increased velocity through the capillaries, although it may be increased in those that terminate directly in the veins; for when we take blood from the arm of a patient in whom the hand is inflamed it flows with great rapidity than under ordinary circumstances. You will perceive from what I have said that the proximate cause of inflammation is still imperfectly understood. The remarks I have now made apply only to acute inflammation, from which I shall now pass to the

chronic form of the disease. Here we have little of the turgescence and redness which characterize acute inflammation. Chronic inflammation would seem rather to be a perverted action of the capillaries, or a disordered state of nutrition. Frequently we discover a deposit of new matter in the part, or augmented secretion from its surface, especially in the case of a mucous membrane. Thickening and enlargement of parts are common consequences of chronic inflammation, which may be considered as a process requiring an increased flow of blood. The spermatic artery is sometimes enlarged to the size of the brachial in chronic diseases of the testicle, as I have several times had occasion to observe.

Surgeons recognise several terminations of inflammation. These terminations are not to be considered as absolute terminations of the inflammation, but as a change in the circumstances of the case, in which the inflammation subsides to a considerable extent, leaving some other form of disease.

After having continued for some time, the inflammation either subsides entirely, and the part returns to a healthy condition, which may be considered a natural and absolute termination; or is succeeded by such a change in the action of the capillary vessels as to produce a secretion of pus. Suppuration, or the formation of pus, is usually set down as one of the terminations of inflammation; but this is by no means the case, forasmuch as inflammation does not always cease when suppuration takes place, although it may be much diminished or modified. Another termination of inflammation, where it ends in the total destruction of the part, is mortification or sphacelus. When inflammation is about to terminate in resolution, the pain is diminished; the effused lymph and serum are absorbed; the swelling, tension, and throbbing subside; the fever and other constitutional symptoms decrease or disappear, and the part returns to its natural state. This is not only the best, but the most common termination of inflammation; and therefore most desired by the surgeon, whose aim is to effect it in all cases where this is practicable.

The French surgeons use the term *delitescence* to represent a very sudden termination of inflammation in resolution. Under such circumstances there is a sudden decrease of pain and disappearance of all the local symptoms, followed by a rapid shrinking and shrivelling of the inflamed parts.

Suppuration is another of the so-called terminations of inflammation, but which would be properly designated as a consequence than a termination. In the process of suppuration the vessels produce pus, which collects in the tissue or substance of the inflamed part, and forms what is called an abscess, or exudes from the surfaces of wounds, ulcers, and the mucous membranes as a discharge. It must be considered as a modification rather than a cessation of inflammatory action: for the parts surrounding a collection of matter are still violently inflamed, and throw out coagulable lymph, which obliterates the surrounding cellular tissue, and prevents further diffusion of the matter.

Another mode in which inflammation is said to terminate is that in which the blood ceases to circulate, and the part becomes cold, insensible, black, and deprived of vitality. This is mortification, which is at the same time the most unfavourable and dangerous mode in which inflammation can terminate. Mortification only occurs when the inflammation has been excessively violent or peculiar in its nature, or has taken place in an unfavourable condition of the system. The influence of the constitutional state, in producing sloughing or mortification, is seen in carbuncles and boils. In carbuncle we have an extensive destruction of the subcutaneous cellular tissue, and a similar slough or core is found in the centre of boils.

Induration was classed by the older surgeon under the term *scirrhus*, and was said to be a termination of inflammation; but you will

readily perceive, from what I have already told you, that induration cannot be properly looked upon as a termination of inflammation. A certain amount of hardness is a common consequence of acute inflammation, as this may sometimes continue for a long time after the cessation of the inflammation.

Another of these so-called terminations of inflammation is when it changes from the acute to the chronic state. When this is the case the symptoms become milder, the redness, swelling, heat and pain subside or diminish, these cases the vessels continue dilated from simple relaxation and want of tone, so that we might be almost tempted to adopt the opinion of Dr. W. Phillip, that inflammation depends on a debilitated state of the capillary vessels.

In inflammation of the eye, for example, the patient is able after a time to bear the light, and feels little pain, but the relaxation and redness of the conjunctiva may continue. When parts have once been the subjects of inflammation they are ever after more disposed to that diseased action, so that repeated attacks of inflammation of some particular organ are commonly observed. Some persons are subject to inflammation of the throat, others to inflammation of the eyes; other, again, to inflammation of the lungs, &c.

Having reviewed the causes and chief phenomena of inflammation, I now turn to a part of the subject of the highest importance and interest—the treatment of the disease—which I must defer until our next meeting.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILSHIRE, M.D. (Edin.), M.B.S.,
Physician to the Royal Infirmary for Children, &c. &c.

(Continued from p. 230.)

I have now, gentlemen, to pass on to a very important and extensive subject—the treatment of scrofula; and here I may remark that it was principally the scope that the consideration of this common malady would afford me, of attending to the great and leading principles of hygiene and therapeutics applicable to many disorders of the infantile and youthful frame, that induced me to bring it so early before your notice. You will not be surprised, then, that I enter into some detail in relation to certain points on which I shall not have hereafter, I think, so fit an opportunity of touching. Many of them will bear quite as intimate a connection with other diseases as they do with scrofula; and, although I say them before you in connection with this decimator of our race, yet I must beg you to consider them as bearing general import.

I would impress upon you, that if the attempt to cure disease after it has invaded the body be a prominent aim of the medical practitioner, and one to which his knowledge of pathology should be considered as always tending, that of endeavouring to prevent its appearance—to protect the body from such invasion—is, or should be, equally as paramount. I am sorry to say, however, that this attempt at prevention of disease is an element of medicine too often lost sight of, and the advice of the professors of our art is but rarely sought for by the public, as either requisite or necessary to be confided in, to point out how it may shun danger, in comparison as to how it may get out of it when it is fairly in.

But, to the philosophical practitioner of medicine, the study of those great principles, of those laws of existence under whose influence the growth, maturity, and welfare of our frame maintained in station of prosperity, according as the body swerves the less from these principles, is equally important and necessary, as the study of those by whose guidance we may restore health to a body which has swerved, or is in fact suffering under disease. The more important, also, will it appear to you, when you recollect that the former study will enable you to preserve a constitution naturally unhealthy, weak, and having peculiar morbid tendencies, from

falling into most serious evils—and which it in many cases most certainly would do upon its departure from the observance of those laws, by attention to which even the most healthy body can in most instances alone maintain its proper balance.

In applying these views to practice—which after all would be of very little purpose were they not so made use of—you will see that a disease may be regarded in two points of light: first, learning its exact nature when fully developed, and how to cure it; secondly, striving to discover its more general causes, and how to prevent it. The grand aim and result of practical medicine are seen, then, as exhibited in Preventive and Curative Therapeutics. Under these two heads I shall discuss separately what I have to say of the therapeutics of scrofula.

When you call to mind that this malady arises from a disorder of the fundamental constitutional powers—that its local evidences are but external manifestations of what we may term a diseased nature of the formative and assimilative functions—it is very plain that great stress must be laid upon an observance of those hygienic laws which, embracing the theories of diet, clothing, and climatal influences, are the main elements by due attention to which we may hope to alter this diseased tendency, or preserve a healthy one from becoming impressed with it. Even in the removal of the local signs of the scrofulous constitution, or the cure of special scrofulous disorders, you must never forget that much of your curative therapeutics will be made up of the principle of hygiene—that, without your paying attention to these, much of your treatment will be but useless attempts at removing that whose more general causes you are refusing to pay attention to.

Now, suppose a child is brought to you evincing the artistic characters of the scrofulous diathesis, and perhaps with these some of the slightest grades of local disorder, eczema, lymphaditis, or conjunctivitis, &c., according to age and other circumstances. Your duty, of course, is to try as far as possible to preserve this child as healthy as you can, to prevent a more severe eruption of inflammatory or tuberculous forms of disorder. The first grand point for you to bear in mind is—that a healthy process of nutrition shall go on in the patient: for without this, any attempt at prevention or cure will be alike useless. In order that this shall take place, the child must be made to live under three great conditions—proper diet, as regard both nature and quantity; preservation of a due amount of animal heat, or proper degree of warmth afforded by external clothing, &c.; proper atmospheric or climatal influences, involving exposure to solar light, exercise, and personal occupations, &c. There are other hygienic principles, of great importance too, but these are the most fundamental.

To begin from the beginning, gentlemen, I shall consider this question—A child is born of a female decidedly scrofulous, is it to be suckled by her? And this question, let me tell you, is by no means so very easy to answer—or rather, it may still be a debatable point. You must excuse me here bringing before you some authorities.

According to Smith, "Where the mother herself is strongly marked by the strumous diathesis, it is the recommendation of the best authorities, that a wet nurse (with the rich) should be procured; with the poor, the child must perforce be brought up by hand." According to Ranking, "The mother ought not to suckle her child, however much she may be prepared to do so, if she or her family exhibit the scrofulous diathesis." Cummin says, "If the child of a scrofulous father is born, unless the mother is free from all traces of the disease, it ought to be consigned to a wet nurse." Evanson and Maunsell state that "Women who labour under any mental or weakening disease, or phthisis, &c., are thoroughly disqualified for the office of nurse." These authorities are sufficient for my purpose, but I might quote others of the same way of thinking too.

Now, if the question be put thus—Should a female who has betrayed marked evidences of the scrofulous diathesis suckle her child, should she be able to procure a good breast of milk for it from a healthier female?—the answer, of course, must be, that she should not. But if it be asked—Should she suckle it if she cannot obtain a wet-nurse, or rather bring it up by hand?—the answer requires considerable reflection ere it be given.

You must recollect, that although—as it is stated—the milk of a tuberculous cow—an animal very subject to such disease, when confined in stables and stall-fed—has been found to contain seven times as much phosphate of lime (a main ingredient of tubercle) as that of a healthy animal, it has not been proved, so far as I am aware at least, the milk of a scrofulous female contains the same; much less are we satisfied that such milk can bestow scrofula on the offspring through the medium of a particular form or contagious principle, although such milk will be a bad article of diet—not so good a milk—not so nutritious a fluid to live upon as that afforded by a woman not scrofulous. The question, then, becomes resolved into this—Will the inferior and less nutritious milk of a scrofulous woman be better for her off-spring than bringing it up by hand?—will the chances for the continuance of its life be greater under the former circumstances than under the latter? My opinion is, that unless the mother is what I may justly call *very scrofulous*, or undoubtedly suffering under tuberculous disease of the lungs, her off-spring will stand a better chance of surviving if she, having quantity enough of milk, perform for the first six months the office of lactation. To lay down the law, that under no consideration is a mother who betrays signs of the scrofulous diathesis to suckle her off-spring, is not only an impracticable theory to carry out, but an unnecessary if not a bad one. Indeed it has been asked by a reviewer, in the "Medico-Chirurgical Review," "where are the wet-nurses to be found for every child of every woman in whom or in whose family there is a scrofulous taint? And what, pray, is to become of the nurses' own poor children, deprived of their natural food, and thereby rendered subject to that very disease sought to be eradicated in others?"

While I give it you as my opinion, then, that it is preferable in the greater number of cases that a child be nursed by a scrofulous mother (under the limitations I before laid down, mind) for the first six months, instead of being brought up by hand, it is also my opinion that at that period she should cease to suckle it, or even before, if the milk become scanty in quantity, or the child dwindle away. And now I may also state another opinion I hold to be true, viz., that one of the main causes of a scrofulous outbreak is not only *undue* or over-lactation by a scrofulous mother, but even by a healthy one.

I have laid down six months as the period at which a scrofulous mother should cease to suckle her child. I would lay down sixteen months as the general period at which a healthy mother should begin to wean the child of a scrofulous father. Of course you must bear in mind there are exceptions to all rules, and that a poor, weak, little thing, almost toothless at this age, may be brought before you, and to whom the good milk of a very sound and healthy mother will be for a longer period of time the best food it can have. There is considerable limit to be allowed, then, as to the continuance or not of nursing such a child.

I must tell you, however, that I do not think there has been advanced in late years a doctrine more tending to increase scrofula and render the life of the woman more precarious and liable to diseases of great debility, and at the same time a more disgusting one, than that promulgated by M. Loudon in his work entitled "Solution du Problem de la Population et du Substante." M. Loudon, amongst other things, would render it a stringent law with women that they should suckle their off-spring for *three years*, as by this means the number of children will be diminished, because, as the doctor says, pregnancy does not

occur during lactation; and he might have added also, because many of the other children will die of scrofula. I will leave entirely out of the question the theory of triennial lactation *preventing* conception, though I would not have you forget that, according to Mr. Robertson, fifty per cent. of the labouring classes of Manchester become pregnant while suckling. But I must put it to the candid judgment of all who are acquainted with the effects of prolonged lactation in this climate, and ask what would be generally the result of three years' suckling upon the present and future health both of the child and the mother?

Whenever I have seen a case of prolonged lactation, the health of the parent has been seriously hurt. But a few weeks ago a female came to me at the dispensary suffering under profuse leucorrhoea and great general debility, loss of appetite, &c. She was a pale, leucophlegmatic person, very much broken down, complaining of all those signs which women do who suckle more or longer than they ought. I inquired if she was nursing. She answered that she had been suckling for three years. Weaning the child, quinine, alum injections, with porter at dinner, has made this woman quite a different thing.

I shall now suppose, from some particular circumstance, a child is to be brought up by hand—in such a case what is it to have? Milk, gentlemen; nothing but milk in most cases; scotch, by all means, sago, arrow-root, semolina, tops and bottoms, biscuit-powder, baked flour, and the whole list of vegetable aliments often so much in vogue. There is not a more fallacious piece of reasoning than that which deduces that such starchy ingredients are either to be given in lieu of, or constantly superadded to, a milk diet. The natural food of a child until it has cut the four central incisor teeth, or is from six to nine months old, is the mother's milk alone; and, if it cannot get that, it should have that which most nearly approximates to it. It is just as bad, also, to give it *solid* food of animal origin before that time; you might as well give it marbles to digest. Not very long ago I was requested to see a child, of a very delicate constitution, who at more than a year old had not a tooth in its head. This child was pining, dwindling away, marasmus daily progressing. I learned it was being fed upon all sorts of things, and at my second visit requested to see the napkin. The dejection chiefly consisted of a few solid hard lumps, of the size of horsebeans, covered with soft white matter. On inquiry, I found that nothing pleased the proud father so much as to make it *sit up at breakfast* and give it bits of bacon to eat. These undigested lumps were the bits of bacon. When I ordered the child nothing but country milk and binglass, it caused some astonishment, as doubts seemed to be held as from whence it could receive nourishment. To enforce this diet I had considerable difficulty. I have lately seen it stated that an experiment of the following kind was made by a distinguished agriculturist, Mr. Smith, of Deanton. At a time when sago was universally recommended as a cheap material for feeding cattle, he purchased a quantity of it, and employed it for fattening a number of calves, substituting the sago for a certain amount of milk. The animals appeared to thrive and grow fat, but in the course of the following year every animal so fed died—some from inflammation, and others from incidental diseases, the accession of which he attributed to the use of sago; the calves fed on milk alone exhibiting no symptoms of unhealthiness. I recommend to your perusal upon this point a review of Liebig and Thompson "On the Food of Animals," in the April number of "Dr. Forbes's Journal." Now, it may be asked, what is the nearest approximating milk to that of the mother? This is an important point to consider, because, you know, not only should the child's food contain certain ingredients, but these ingredients should be present in the proper proportion. I think, taking all things into consideration, we may place the following milks in this pro-

gression:—Those of woman, ass, goat, cow, ewe. You know, perhaps, that the grand characteristic of woman's milk is, that it contains but little caseine, or cheesy matter; but much sugar; and in these two important points the milk of the ass most nearly approximates. But, of course, it is but comparatively few persons who can afford to go on buying ass's milk for a long period. But every person can procure cow's milk; and, such being the case, you must endeavour to make that *artificially* approximate, which does not *naturally*. So to the best, of country cow milk, that can be obtained, about one-third of tepid water should be added to dilute it (for it is too strong in cheese), and also sugar, for in this it is naturally deficient. In administering this food, if two sucking-bottles can be procured, so as to prevent accumulations and acidity in a constantly-employed one, they will be found a better medium than the spoon. Sometimes you will find that, if diarrhoea comes on, the milk boiled will be best; at other times it will not suit at all, but isinglass-pap will be of avail. Often you may have to dilute the milk much more than is usual at other times not. I cannot agree with those who recommend, under ordinary circumstances, at a very early age, "light beef or chicken tea;" and it has fallen to my lot to bring back a child to health by simply reverting to a milk diet alone, which was progressing in disease, subjected to another now and then. Of course you may meet with cases in which strong beef tea or gravy, with the fat skimmed off after it has been allowed to cool, is a useful resource; but such are exceptions to the general rule, mind. As a child gets more teeth, lateral as well as incisor, indication is given that variety will be proper in the food, and various vegetable aliments are now to be superadded with those of animal origin. Of course, in such a disease as scrofula, the diet is to be good, at the same time time that the stomach has not given to it to do what it cannot accomplish, either in quantity or quality. If, however, complete mastication can be performed, meat is to be given before that time; very often a piece of soft meat may be offered to the child to suck. As the child gets older the chief indications are, that the diet be substantial and in proper quantity; whilst the array of puddings, pie-crusts, and confectionery be entirely abrogated, as well as sloppy, thin vegetable makeshifts. Eggs and milk are always good; but a scrofulous diathesis always needs meat, and it is a very good plan to let it have some at breakfast. Corned or salt beef, ham, and the like, are difficult of digestion, and otherwise improper; the lean of pork may be used occasionally; but fat bacon, which is so frequently used, and in some agricultural districts to the exclusion of every other kind of meat, is detrimental in the extreme. It may appear to you that advice about the necessity of substantial food such as meat is not necessary, save with the inferior class of society, whose means too often prohibit them from its employment. But this is by no means the case, for there is a middle, and what is called a better, class of society, in which animal food forms a diminished article of diet, and this also for economy. Nay, you will find in the better-cultivated links of the social chain, as in the families of professional men of all kinds, of men working more with the head than with the hand, where there are large families and not an extensive means, but where still appearances must be kept up, that it is not uncommon for the mother to "make up" the dinner with puddings, pies, &c., and hence, if the children get but little meat at dinner, they get it at no other time of the day; it is not seen by them at breakfast, and if old enough to get supper, if supper be had instead of late tea, they get bread and cheese. With respect to the female children of this class of society, this holds good more than with the boys, especially as the latter get older: they are sent out to an office or other employment even at fourteen, if not before, and dine at an eating-house; but the sisters are at home eating puddings and bread and butter, and perhaps, to

reserve a due degree of fashionability, their diluent is water at the one meal, at the others washy tea. I mentioned cheese just now: I should have told you, *en passant*, that if the stomach can digest cheese it is highly nutritious as a secondary or condimentary article of diet, and may as such be allowed. I have not alluded specially to diluents. The chief things you have to take care of is, that children do not get things like wine, spirits and water, and stimulating cordials; such things are only to be given under your own or other medical advice. In a great many cases common table-beer, if not acid, will be proper to be taken at dinner; but in most, when the child is not weak, milk or toast and water will be sufficient. There are other cases, however, when at a very early age good porter is to be allowed; I have several such, between two and three years of age, to whom I order porter with the best results. I have even given it with advantage to a child only fifteen months old, not as a temporary stimulant, but as a prolonged article of diet. These of course are cases of considerable debility, and the children thin and pallid. At breakfast and the evening meal, &c., milk is to be taken, by no means tea.

DUMAS ON ORGANIC CHEMISTRY. No. XX.

(Continued from page 213.)

ON THE DIGESTION AND ITS PRODUCTS.

The phenomena of respiration, by destroying the materials rendered unfit for life, necessarily lead to losses in the organism which the nutritive functions are called on incessantly to repair. The blood conveys into the economy the destroying element—oxygen; but at the same time it carries the reparative materials in exchange for those which the vital processes have withdrawn. In the normal state, the elements with which the blood is charged, and which ought at the same time to suffice for the wants of respiration and for those of the nutritive functions, are furnished to it by the aliments. But the varied substances entering into the composition of the food ordinarily pass into the blood only after having undergone, in the interior of the economy, certain modifications which render them fit for the office they are called upon to perform. These changes are accomplished in the digestive apparatus, where the masticated aliments are retained for a certain time, and where they become impregnated with the liquid capable of dissolving or dividing them. These liquids are—the saliva, the gastric juice, the bile, the pancreatic juice, and the intestinal secretion. The action which these fluids exercise on the alimentary substances is a purely chemical one. The constitution of these different products becomes, therefore, a consideration of great importance in the investigation of the phenomena of digestion. We are already acquainted with the composition of the bile; it remains for us, then, that we may be enabled fully to comprehend the chemical phenomena of digestion, to study the nature of the other liquids which we have just named.

Saliva.—The saliva is the product secreted by the salivary glands. It is a viscous, ropy liquid, generally somewhat thickened by mucus, which separates from it by repose. In the normal state it is always alkaline—a property which it owes to a small proportion of soda which it contains. In certain pathological states, especially in some gastric affections, the saliva becomes acid. When the salivary secretion is copious, it always possesses an alkaline reaction; when, on the contrary, it is sparing, it becomes acid, and produces in the mouth a peculiar sensation of dryness and harshness familiar to most people. From the foregoing, it is evident that the saliva, in the state in which we meet with it, is the result of two secretions, the one of which, being acid, is supersaturated by the other, which is alkaline. Its reaction on litmus-paper depends on the predominance of the one or the other of

these two secretions. Supposing such to be the case, the formation of the deposit known by the name of tartar, and which is constituted by a mixture of the insoluble phosphates and mucus, may be readily explained. We know, in fact, that all the acid liquids of the economy contain phosphates in solution; but so soon as the free acid is saturated, these phosphates are deposited in an insoluble form.

The density of saliva varies between 1.004 and 1.009. It leaves, after evaporation, a solid residue, amounting as high as 8 or 12 per 1000.

The following is the analysis of this fluid, made by Berzelius:—

Water	992.0
Ptyaline	2.9
Mucus	1.4
Animal matter and alkaline lactates	0.9
Chloride of sodium	1.7
Soda	0.2

1000.0

MM. Tiedemann and Gmelin analyzed some human saliva which had been collected during smoking. They found in it the following principles:—

Matter soluble in alcohol and insoluble in water: phosphorated fatty matter; matter soluble in alcohol and in water: animal matter, chloride of potassium, lactate of soda, sulpho-cyanide of potassium	31.25
Matter deposited on cooling from boiling alcohol, with a little sulphate of potass and chloride of potassium	1.25
Matters soluble in water: ptyaline with a large proportion of alkaline phosphates, and a little sulphate and chloride of potassium	20.00
Matters insoluble in alcohol and water: mucus, probably a little albumen, with alkaline phosphates and carbonates	40.00

92.50

The loss appears to be owing to the water which the matter had retained.

M. C. G. Mitscherlich analyzed some saliva collected directly from a fistula of the Stenonian duct. He observed that the secretion of the saliva was more abundant at the commencement of a repast than towards its close; that during meals it had an alkaline reaction, but that in the intervals it reddened litmus-paper. The density of the saliva thus collected varied from 1.006 to 1.0088; by evaporation, it left a solid residue averaging from 1.47 to 1.63 per cent. in weight; 66.5 grammes of saliva were found to contain 0.061 gramme of insoluble matter, or about one-tenth per cent. This quantity of saliva, evaporated in vacuo, left a residue of 1.121 gramme, of which 0.281 gramme was insoluble in water and in alcohol, 0.352 soluble in water and insoluble in alcohol at 80°, and lastly 0.192 soluble in water and in alcohol.

One hundred parts of this saliva required, for its neutralization, from 0.196 to 0.223 of sulphuric acid, which corresponds to 0.153 and 0.174 per cent. of soda. By incineration, it left about one-half per cent. of ashes, containing:—

Chloride of calcium	0.180
Potass combined with lactic acid	0.095
Soda	—
Soda very probably combined with mucus	0.164
Phosphate of lime	0.017
Silica	0.015

The filtered saliva, when cold, is rendered cloudy by alcohol and tannin; this muddiness is removed by heat, but reappears so soon as the liquid becomes cold again.

Among the saline products which disappear during the process of incineration of the saliva, we may reckon the sulpho-cyanide of potassium. Treviranus was the first to observe that the saliva possesses the property of turning red with the solutions of the salts of the peroxide of iron. MM. Tiedemann and Gmelin have proved that this property depends on the presence of a sulpho-cyanide.

The peculiar organic matter to which the saliva

owes its viscosity has received from M. Berzélius, who was the first to isolate and study this substance, the name of *ptyaline*. The following is the process used for extracting it:—We evaporate the saliva to dryness; the colourless and gummy residue is treated by alcohol, which removes from it a small quantity of soluble animal matter, some salts, and a little fatty principle, in which the presence of cholesterine is at times discovered; the insoluble alkaline residue is treated by acetic acid, evaporated to dryness, and then acted on again by alcohol. The residue from this second treatment consists of some mucus, which constitutes nearly a third of the whole mass, and ptyaline. The latter is to be isolated by dissolving it in water and then evaporating the solution to dryness.

When brought into contact with water, ptyaline is at first whitened, and subsequently it becomes completely dissolved, at the same time communicating to the water that ropy appearance peculiar to saliva. This solution is not thickened by heat, by the acids, or by the basic bodies. None of the salts precipitate it. Alcohol alone renders it cloudy, when not too much diluted.

The saliva has been but very little examined in animals. Gmelin and Tiedemann have found the saliva of the dog richer in solid materials than that of man: it yielded 2.58 per cent. of fixed matters and salts, analogous to those which have been found in the human saliva; they also discovered in it a small quantity of phosphates and of earthy carbonates.

The saliva of the horse, again, appears to be a little more concentrated. F. Simon states that he has found in it a considerable quantity of caseine. C. H. Schultz has made a similar observation.

The following is M. Simon's analysis:—

Water	982.0
Fatty matter, containing cholesterine ..	0.1
Ptyaline and extractive matter ..	4.1
Caseine	5.4
Albumen	0.6
Extractive matter and salts	7.2

The saliva of the sheep has been analyzed by MM. Tiedemann and Gmelin, who found it to possess a composition very analogous to that of man: it contained 1.58 per cent. of solid residue. MM. Leuret and Lassaigne have arrived at similar results.

We have already spoken of the deposit which is sometimes formed on the teeth, and which is known under the name of *tartar*. Annexed are some analyses of this matter, made by MM. Berzélius, Vauquelin, and Laugier:—

Ptyaline	Berzélius.
Mucus	1.0
Earthy phosphates	12.5
Animal matter, dissolved by hydrochloric acid	79.0
	7.5

100.0
Vauquelin
and Laugier.

Water	0.07
Mucus insoluble in water and acids ..	0.13
Phosphate of lime, trace of magnesia ..	0.66
Carbonate of lime	0.09
Organic matter, dissolved in hydrochloric acid	0.05
	1.00

The salivary glands sometimes contain concretions. We here give some analyses of these bodies:—

	Caventou.	Lassaigne.	Henry.
	The ass.	The horse.	The horse.
Carbonate of lime	91.6	84	85.5
Carbonate of magnesia	—	—	7.6
Phosphate of lime	4.8	3	4.4
Animal matter	3.6	9	2.4
Water	—	3	—

According to M. Wurzer, the salivary concretion of the horse contained:—

Carbonate of lime	80.50	87.5
Phosphate of lime	2.75	3.5
Soluble animal matter	8.60	7.0
Insoluble animal matter	4.40	—

Oxides of iron and of manganese

Chloride of sodium	1.00	—
Chloride of sodium	1.00	0.5
Carbonate of soda	1.75	0.9

Gastric Juice.—The gastric juice is an acid liquid which is secreted in abundance by the stomach during the act of digestion. In the normal state, it is colourless and inodorous; it possesses a salt and manifestly acid taste. It putrefies with great difficulty, and preserves for a long time animal matters which are impregnated with it. The liquid which bathes the walls of the stomach, during the intervals of digestion, does not appear to be gastric juice; at least it is neutral to litmus-paper. Various opinions have been formed as to the chemical nature of the gastric juice. There is, however, no doubt but that it contains a principle analogous to diastase, and which has been already described under the name of *pepsine*, *chymosine*, or *gasterase*.

With regard to the acid reaction possessed by the gastric juice, it is easy to prove that it is not exclusively due to biphosphate of lime, as was recently advanced by M. Blondlot, but rather to the presence of a free acid. In fact, if we adopt the experiment of M. Melsens, by placing gastric juice, for twenty-four hours, in contact with Iceland spar in a well-stoppered bottle, shaking it up from time to time, we shall see the crystals of carbonate of lime, while being corroded by the acid, become opaque and lose a portion of their substance. Biphosphate of lime could not give rise to this phenomenon, which can be due only to the presence of a free acid.

Numerous and contradictory data have been formed relative to the chemical nature of this acid. Prout, who was the first to analyze the gastric juice of different animals, asserted that it contained hydrochloric acid. His observation has been confirmed by Tiedemann and Gmelin, who, moreover, pointed out the presence of acetic acid in the gastric juice of the dog, and of acetic and butyric acids in that of the horse. M. Schultz has also demonstrated the existence of a volatile acid in the chyme of different animals, which he distilled over with water; but, according to his experiments, this was not hydrochloric, but acetic, acid. Very recently, MM. Bernard and Barreswill have repeated these experiments, but they arrived at results altogether different. According to these chemists, the gastric juice contains neither true acetic acid nor acetates; and the hydrochloric acid, which we obtain as a consequence of distillation, is formed merely by the action of a fixed acid on the alkaline chlorides existing in the liquids of the economy. MM. Bernard and Barreswill believe that they may conclude from their experiments, that the gastric juice contains lactic acid and some phosphoric acid in a state of liberty. The first of these acids had been previously pointed out by M. Chevreul, as well as by MM. Leuret and Lassaigne. The presence of butyric acid in the gastric juice has not been confirmed.

Pancreatic Juice.—The pancreatic juice is secreted by a large gland, situated behind the stomach, between the spleen and the duodenum. It is a viscous liquid, transparent and slightly opaline; it possesses a saltish taste, and has a similar consistence to that of the serum of the blood.

MM. Tiedemann and Gmelin collected the pancreatic juice of a large dog, by placing a glass tube in the pancreatic canal. The first few drops which escaped were feebly acid, whilst the latter portion had an alkaline reaction. These chemists discovered the same properties in the pancreatic juice of a sheep. On the other hand, MM. Mayer, Magendie, Leuret, and Lassaigne always found it to possess an alkaline character: an observation which has since been confirmed by MM. Bouchardat and Sandras.

The pancreatic juice appears to contain a certain quantity of albumen; at least, it is partly coagulated by heat. It contains eight per cent. of solid residue. Annexed are two analyses of the pancreatic juice of the dog and of the sheep, made by MM. Tiedemann and Gmelin:—

	Dog.	Sheep.
Water	917.2	968.5
Extractive matter and salts soluble in alcohol	36.5	18.5
Caceous matters soluble in water, and salts	15.8	2.8
Albumen and salts	35.5	22.4

MM. Louret and Lassaigne found that the pancreatic juice of the horse had the same composition as the human saliva. It is very probable, in fact, that, like this liquid, it contains an azotized principle analogous to diastase. MM. Bouchardat and Sandras have proved that the pancreatic juice of the hen rapidly transforms starch into dextrine and glucose. Lastly, we should add that no sulpho-cyanide has yet been found in this liquid.

According to MM. Bernard and Barreswill, the pancreatic juice is analogous to the saliva, but richer in active principles. When rendered acid, it is capable of acting like the gastric juice, and would be able not only to replace it, but it becomes even still more energetic in character.

Intestinal Juice.—The numerous follicles of the intestine secrete a liquid which appears to have a composition and properties analogous to those of the gastric juice. It is impossible to collect the intestinal juice in a state of purity: it is always mixed with mucosities, bile, and pancreatic juice. MM. Tiedemann and Gmelin have found in it a little free acid, albumen, a matter analogous to caseine, a substance precipitable by protochloride of tin which they regard as analogous to ptyaline, a little biliary resin, some salts, and undetermined animal matters. The intestinal juice collected in the lower half of the intestine has a neutral reaction. The mucosities of the cæcum always present an acid character in dogs. Bicarbonate of soda has been found in the cæcum of the horse. In that of the rabbit, M. Viridet has observed an acid reaction similar to that in the stomach.

ORIGINAL CONTRIBUTIONS.

A STATISTIC AND CRITICAL REPORT OF THE EFFECTS OF ETHERIC INHALATION, FROM CASES RECORDED IN THE HOSPITALS OF PARIS.

Translated from the Original of Dr. BURGUIERES.

(Continued from p. 231.)

THE MOTIVE STATE.

The faculty of motion under the influence of ether appears to be in many cases very irregular and incomplete. The disordered movements of the body, which usually take place during the first period, may continue during the second and the third, although the etherization shall produce its other effects. In some cases these movements are suddenly brought into action, although the patient appeared to be in a profound sleep. On many occasions they have assumed a convulsive character, and M. Jobert records one in which it took the form of tetanus. Besides the grave importance of such accidents in themselves, we must consider the embarrassed position into which the operator may be thrown. It is for this reason desirable that the influence of etherization should be previously tried on the susceptibility of the invalid. We should also adopt every precaution to assure ourselves of the perfect stillness of the patient. In reference to this subject, unforeseen accidents have been spoken of, where patients have escaped, streaming with blood, from the hands of the operator. We think an avowal of these accidents will be sufficient to prevent all fear of their recurrence. Whatever may occur, if the motive power be not as completely extinguished as the sensibility, the evident and alarming difficulties which may result from motion are met with only as the rarest exceptions.

We shall here relate two facts, noticed by M. Velpeau, in which the powers of motion were differently affected by ether in the two sides of

one body: although the muscular relaxation existed in one side, the other presented contraction, and the relaxed limbs were those on which M. Velpeau had to operate—in the one case to reduce a luxated limb, and in the other a fracture.

DURATION OF ETHERIC INTOXICATION.

The etheric slumber has lasted, with its different characteristics, from two minutes to forty: the ordinary duration is from four to ten. M. Roux thinks he has remarked that in general the sleep lasts in proportion to the time it has been found necessary to administer the vapour. This rule, however, suffers by numerous objections.

PHENOMENA WHICH OCCUR AT THE TIME OF WAKING.

As soon as the ether which has been absorbed begins to lose its influence, the power of sensibility is the first which usually re-assumes its normal character. It has frequently occurred that patients, who were at first in a state of perfect insensibility, have exhibited symptoms of pain during the last part of the operation, on applying ligatures to the vessels, or at the time of dressing, and before the powers of recognition were restored. The waking of the intellectual faculties, which is not long delayed, is often marked by certain phenomena analogous to those of excitement, and occur at the commencement of etherization. That of the cheerful kind is here again the most common; but sometimes we have witnessed considerable irritation. This light delirium is never of long continuance.

It sometimes happens that the intellectual power is the first to be re-established, although the insensible state is continued for a greater or less period. It is now that the patient finds himself in that singular position already alluded to, in which we discover the mind entirely undisturbed, while the powers of sensation are totally extinguished.

In most cases a perfect calm succeeds the phenomena of etheric intoxication. In one instance only has there occurred a case of syncope, which lasted for some minutes. Sometimes there has appeared a slight pain or heaviness of the head, excitement, cough, and a disagreeable taste of ether. These appearances were of no importance, except in one case, noticed by M. Jobert, which will presently be considered in connection with the subject of consecutive accidents.

OPERATIONS IN WHICH THE EFFECTS OF ETHER HAVE BEEN USED TO ADVANTAGE.

The following table, in which the facts are arranged according to the nature of the operations, will afford some idea of the different applications to which the etheric sleep has been directed:—

Amputation of the thigh	10
Amputation of the leg	8
Amputation of the arm	4
Amputation of the forearm	1
Partial amputation of the foot	2
Partial amputation of the hand	1
Amputation of fingers and toes	19
Total and partial amputation of the breast	8
Extirpation of important tumours in different regions	12
Extirpation of tumour in the eye	1
Sarcocoele	
Strangulated hernia	
Stone	
Lith-trity	
Hydrocele	
Varicocele	2
Phimosia	4
Fistula, or fissure in ano	8
Reducing luxations or fractures	5
Reducing hernia	1
Removing nails	4
Extirpating glands of the throat	1
Polypus of the nose	3
Cataract	1
Fistula lachrymalis	1
Strabismus	2
Aversion of tendo Achillis	2
Actual cautery	12
Application of moxas	2
Opening abscesses, incisions, excisions, &c.	91

It is for the amputation of limbs that etheric inhalation has been most frequently employed, and with the greatest success. These amputations are in effect very painful operations; they disturb the whole system to a considerable extent, and the mind of a patient who sees himself deprived of a portion of himself is always subjected to a severe shock. The advantages, therefore, which are obtained in these operations by the sleep and insensibility produced from etheric inhalation may be readily understood; let us also add that amputations are rapidly performed, and are consequently disposed of under one inhalation. It has, however, been supposed that the muscular relaxation produced by ether might oppose itself to the regularity and proper conformation of the stump. This apprehension cannot be justified by experience: a loss of muscular tension is not a permanent consequence of etheric inhalation; besides which it is well known that relaxation does not prevent the regular conformation of stumps. It is not easy to produce on the dead subject the hollow conic stump in perfect accordance with the rules of science.

We have easily been able, during the process of amputation, to examine the qualities of blood, which some physiologists declare to be profoundly altered by the ether. M. Amussat, among others, concludes from experiments made on animals, that the arterial blood becomes black, and presents the ordinary appearance of venous blood. On the other hand, experiments made at Alfort, by M. Renault, have produced results different to those of M. Amussat. Does not this modification of arterial blood, discovered by this last experimentalist, belong more to asphyxia, under which these animals expired, than to the direct action of ether upon the blood? Whatever the fact may be in this respect, the greater part of our surgeons agree in stating that the blood which flows from the vessels in consequence of amputation presents no change worthy of consideration. This alteration, if any can be proved, does not belong to the surgical period. We are bound, however, to notice that M. Jobert has found in some cases that the arterial blood, without being positively black, was less crimson red. May not this have been caused by the extent to which the etherization had been carried?

The eight total and partial amputations of the breasts—the twelve extirpations of tumours, important from their size—produce, together with the removal of the eye, and the operation for sarcocele by M. Velpeau, results similar to those of limb amputations.

Of those operations which are the most painful, if not the most serious, we must particularly notice that of forcibly removing the finger-nail: this has been performed four times without producing the slightest pain. Twelve times has the actual cautery—that painful and frighful resource of the invalid—been employed without one shock upon the nervous system.

The operations to which we are now proceeding to refer are simple and quick of execution; and here the etherization presents itself with every advantage. The possibility of its application under some circumstances has been questioned—whether arising from the difficulties of manual operation, whether in consequence of the duration being necessarily prolonged, or from the seat of the disease. M. Robert, on application of the ligature to the carotid artery, did not think it necessary to resort to etherization; M. Paul Guersant also abstained from its use in a case of strangulated hernia; and M. Roux did not have recourse to it for operation in a case of cataract. For this last operation an experiment made by M. Gerdy holds out no encouragement to the surgeon; having etherized a patient whom he proposed to operate on for cataract by the method of extraction, he was obliged to interrupt the operation already commenced in consequence of a convulsive movement which affected the globe of the eye. M. Langier met with the same accident while removing a staphyloma from the cornea. On the other hand, however, some operations performed upon the eye and its con-

nected parts have perfectly succeeded. M. Roux has performed without accident the operation for fistula lachrymalis; MM. Bouvier and Vidal, that for strabismus.

Some difficult and delicate operations have been successfully performed on other parts. M. P. Guersant has removed the stone with perfect success from a child of eight years old. M. Michon has performed lithotomy, for which M. Leroy d'Etoiles had already used etherization. Finally, M. Langier has performed an operation for strangulated hernia which has perfectly succeeded, although the strangulation had continued for sixty hours, and the patient was reduced to a very dangerous state.

For all the preceding facts we are specially indebted to the state of insensibility and sleep. The muscular relaxation which ether sometimes produces can be advantageously brought into use. By this means the reduction of fractures and dislocations have been five times accomplished. The case in which this result has proved the most remarkable is that reported by M. Velpeau. He succeeded on a powerful young man suffering under dislocation of the left hip. It was impossible to touch the thigh of this youth without his yielding to the loudest cries of agony; many attempts were made without success to reduce the luxated joint; the unfortunate man, yielding to the agony of his torments, implored to be supplied with ether. The inhalation was accordingly effected, and in two minutes, by a succession of methodical pulls, much less forcible than those used in ordinary cases, the dislocation was reduced with the greatest ease.

As spasmodic contraction of the muscles occurs sometimes in strangulated hernia, it has been suggested that etheric stupefaction should be applied in such cases. The only fact of this kind noticed in the hospitals belongs to M. Gerdy, who etherized a patient to return a rupture that had been operated on some few days previous, but had fallen out again. The case is far from being so conclusive as that reported in the *Augsburg Gazette*, and copied out of a letter from Venice. A man suffering from hernia was to have been operated on at the hospital; an incision of the abdomen was considered necessary, and, to place the patient in a complete state of repose, he was made to inhale the ether about ten minutes. At the moment when the operator took the disengaged part to show his assistant in what position he was to hold it, the gut returned spontaneously to its proper place, and the patient was cured without an operation.

In our table of recapitulation will be seen a considerable list of simple incisions and very light operations. We have already observed that this fact should be attributed in a great degree to the anxiety which nearly all our patients exhibit to secure the privilege of being etherized; nevertheless we are of opinion that, however rare and inconsiderable the inconveniences may be which result from etherization pushed to a certain limit, we ought not to concede without some reluctance to the wishes of the sick when operations of trifling importance are required.

PHENOMENA CONSECUTIVE AND THE RESULT OF OPERATIONS PERFORMED UNDER THE INFLUENCE OF ETHER.

The point which now remains to be examined is one of the last importance. It is in fact necessary to ascertain, as some of the adversaries to ether have presumed, whether the perturbation produced in the system by this substance can compromise effects of operation or aggravate the consequences. The first expedient for resolving this question which presents itself naturally to our mind consists in an investigation of what are the cases in which the operations have been followed by death, and to compare the proportion of deaths which have followed operations performed under the influence of ether with those furnished by the same operations made under ordinary circumstances. Let us interrogate for this purpose our statistics.

In the first place, then, the following is a table

of operations which have been followed by the death of those invalids submitted to the inhalation of ether:—

Amputation of the thigh	...	4
Ditto leg	...	3
Ditto arm	...	2
Ditto forearm	...	2
Ditto toe	...	1
Ditto finger	...	1
Ditto breast	...	2
Extirpation of tumours	...	2

17

Let us compare these results with those we find in an interesting work published in 1842, by M. Malgaigne, in the "Archives de Médecine," and having for its title, "Etudes Statistiques sur les Résultats des Grandes Opérations dans les Hôpitaux de Paris." We learn by this work that from the 1st of January, 1836, to the 1st of January, 1841, there were performed in the hospitals 558 amputations of limbs, from the disarticulation of the thigh to amputations of the finger and toe. The mortality was 332, or about two in five.

On amputations of the same kind performed under the influence of ether, we find, after subtracting those deaths resulting from amputation of the breast and the removal of tumours, that our table gives twelve deaths in forty-five cases, being upon an average of one in four—a proportion very much in favour of the ether.

But, as M. Malgaigne remarks, these generalities are not satisfactory, it is necessary to distinguish the greater from the less important amputations. If, then, we take the total amputations of the thigh, the leg, the arm, and forearm, we find the number of operations, which have resulted in ten deaths, to be twenty-five, the aggregate being about two in five. The calculation made, however, by M. Malgaigne, gives, on the contrary, 512 amputations of the same kind, and 281 deaths, or nearly three in five. Here we again find that our investigation is by no means unfavourable to the use of ether.

Our trials are not as yet sufficiently numerous to admit a similar calculation on every kind of operation. We must, nevertheless, notice that out of ten amputations of the thigh, there have followed four deaths, being two in five; while the preceding statistics of the hospitals furnish 126 deaths on 201, or three in five.

We shall not draw from these numbers, which are of only small consideration, the ultimate conclusions anticipated in favour of ether. They disturb, however, in no degree the following truths proclaimed by M. Velpeau, "that ether, by preventing pain, does not deprive operations of their dangerous consequences, and that the means of operating without pain to the invalid cannot justify the expedient without the aid of necessity."

If, however, we pay careful attention to these observations, we shall discover that of the consecutive phenomena very few can be traced to the effects of ether. M. Jobert attributes, nevertheless, some accidents to the use of this substance. He has observed severe bronchitis in several cases of persons operated on; indeed, he noticed in one case a spasmodic convulsion of the stump, followed by tetanous contraction of the whole body. This patient died, and "it is evident," observes M. Jobert, "that the ether was not a stranger to his death."

After what M. Majendie has said concerning the fluidizing action which ether exercises on the blood, there might be some reason to fear a development of those consecutive hemorrhages which sometimes occur through exhalation to the surface of wounds, although the vessels may have been most securely tied. Observation does not justify our apprehension. In one case only have we noticed hemorrhage, and this was sufficiently accounted for by the weakness of the patient and the nature of his disease, which had produced a considerable derangement in the vascular system.

Many surgeons, particularly MM. Velpeau, Jobert, and Malgaigne, have remarked that in

general there has been less reaction on those who have been operated on with ether. The fever which is called *traumatique* is with them less violent than in ordinary cases. The local inflammation of the wound has also proved, in many instances, less considerable under the observation of M. Jobert, which appears to this surgeon a reason why the union of wounds by the first intention has in some cases been opposed. Those observations which relate to the influences ether may exercise over the *traumatismes* require proofs; but, as they have been made by several surgeons, we have considered it our duty to record them. We shall now direct our attention to the most important peculiarities which etheric action has produced by its application to surgical operations. It will be seen that practice is very far from justifying the fears expressed by some persons, that the employment of this accessory would be attended with danger. It has, no doubt, its inconvenience; but it must not be denied that, employed with caution, its action watched and carefully directed, it has been called into existence for the purpose of rendering vast services to the science of surgery.

It only remains for us to allude to the employment of etheric inhalation in childbirth, and in the treatment of some diseases; this we shall do in some future article.

(Signed)

DR. BURGHIÈRES.

ROYAL BERKSHIRE HOSPITAL.

SURGICAL REPORTS AND OBSERVATIONS.

By F. A. BULLEY, Esq., F.R.C.S., Surgeon to the Hospital.

There are no accidents to which the human frame is liable, the treatment of which has been so various or undeterminate, as that of injuries by fire. In one class of cases it has been recommended that stimulating applications should be used; in another, that they should be of a sedative nature; while in many uses the exclusion of the air from the burnt surface has been supposed to be of the first importance; but, whatever may have been the means suggested for their relief, they do not appear to have been formed upon any fixed principle, and every medical practitioner must at times have found a difficulty in determining which of the many different methods would be the best to be adopted in an emergency of this kind.

I shall, therefore, be excused for relating a few cases illustrative of a simple mode of treatment which, as far as I am capable of judging, is applicable to burns of every degree of intensity, and which I have been in the habit of employing for several years past, both in hospital and private practice, with the most satisfactory results.

The remedy in question consists in the application of treacle and water, in the proportion of one part of the former to three of the latter, over the burnt surfaces, at a temperature of 98°, by means of lint soaked in the solution and laid over the whole of the injured parts. This dressing is to be changed night and morning, the lint having been kept moist during the day by occasional saturation with the mixture of the same temperature, most readily done by soaking a sponge in the fluid, and at intervals squeezing its contents over the lint while still in contact with the surface. The constitutional means to be adopted will be best understood from a perusal of the accompanying cases.

CASE I.—Martha H., aged sixteen, was admitted into the hospital, Oct. 7, 1846, on account of a burn which she had received by the explosion of a box of gunpowder, that had been left in a cupboard, to which she had inadvertently gone with a lighted candle. Half an hour had elapsed since the occurrence of the accident before I saw her, when the following appearances of injury presented themselves:—Her face, which was of a much darker colour than natural, and enormously puffed and swelled, was in the most agonizing pain, and it would have been impos-

sible for her most intimate friend to have recognised a single feature, so great was the disfigurement of her countenance. Her eyes were deeply sunk in the surrounding swelling, with great puffing of the lids, so that it was impossible by any means to ascertain whether the eyeballs had been injured or not, by the fire; the whole skin of the face and eyelids were in a state of active inflammation, which appeared to have been increasing during the short time which had elapsed since the occurrence of the accident; the forehead, and at least one half of the hairy scalp, were in the same swelled and puffy state, the hair having been burnt off close to the skin. On the fore part of the neck the injury extended from just below the angle of the jaw on the left side, down towards the left mamma; and in a large portion of this burnt surface the skin and subjacent cellular tissue were destroyed, the former having assumed the dark brown hue indicative of its complete disorganization. Both arms, from the shoulders downwards, and in the whole circumference of the limbs, were burnt in the same degree as the face, but without abrasion of the surface; the whole of the integuments with the exception of a patch on the upper part of of the arm, near the left shoulder, which had been more deeply injured, being in the same reddened, swelled, and violently inflamed state. The skin of the hands and fingers had been completely rubbed off, owing to her having hastily laid hold of the handle of a pump, in her endeavour to get some water to assuage the pain. There were several large and deep burns over the fore part of the chest, where the skin and cellular membrane had been entirely destroyed.

The treatment immediately adopted was the application of lint, saturated with the mixture of treacle and water warmed, over the whole of the injured surface, with the exception of the hands, which were carefully dressed with simple cerate, to prevent adhesion of the raw surfaces between the fingers. The direct effect of the application was a slight increase of the pain, which lasted for a few minutes, and then subsided, leaving her comparatively free from the intense and burning heat from which she had just previously been suffering. After the first day or two she felt no pain on the application, but only its soothing effect, which every day became more and more apparent. Sometimes the dressing, though not painful, was very fatiguing, so that it was necessary to give her a little wine, which was more necessary when the extensive surfaces began to discharge pus.

Altogether, the treacle dressing was employed for six weeks, using it morning and evening in the same manner as when first applied. For the first fortnight she was much troubled with a feverish thirst, which left her, however, at the end of that period; but she never had any particular rigors, or, with the exception of occasional slight pains in the chest, any such internal uneasiness as would indicate a disposition to metastatic inflammation of any kind.

At the end of six weeks the inflammation, which had more or less affected the whole of the injured parts, had nearly subsided, and the skin of the arms, after having been covered with a purulent incrustation, which had once or twice exfoliated and reappeared, had assumed in a great measure its natural appearance, with the exception that in the upper parts, where it had been more deeply burnt, the hollows formed by the loss of the integument and cellular tissue still exposed a large granulating surface, but perfectly smooth and level.

The skin of the face and head had undergone the same change as that of the arms, having become covered once or twice with the same kind of purulent crust, which had afterwards exfoliated, leaving the cuticle smooth and unaltered, with the exception of its having assumed a brownish colour, which remained for some time after her discharge.

After this period (six weeks from the date of the accident) simple cerates only was applied to the granulating surfaces, the carbonized skin having become wholly exfoliated; and the treacle

dressing was used to the sound integument surrounding them, with a view to soften it and give it an additional extensibility, and allow of its being drawn more evenly towards the centre of the wounds in the progress of healing, which in some cases it seems capable of effecting, and to which in some measure I attribute the smoothness of the cicatrices, and the absence of puckering in the neighbouring integument, which I have reason to believe is occasionally obtained by this mode of treatment.

The cure was, as is usual in such cases, somewhat tedious and protracted; but on her discharge from the hospital, at the end of four months and a half, all the wounds had healed, and, notwithstanding the original amount of injury (considerably more than a fifth part of the body having suffered from its effects), little or no contraction was perceptible at any part—a result, from the apparently hopeless nature of the accident, at first scarcely to be anticipated. The internal remedies had consisted of small doses of syrup of poppies, frequently repeated, with, as circumstances required, more powerful opiates, also occasional doses of castor oil, as the most un-irritating aperient, and as least calculated to favour the occurrence of meta-static intestinal irritation, which saline and drastic purgatives would appear in some cases to do. It is a remarkable circumstance that, during the whole period of treatment, there was an entire absence of any odour of putrescence, as accompanying the putrefactive decomposition which usually follows the destruction of living parts by fire.

CASE II.—Alice A., aged nine years, admitted Dec. 8, 1846. She had been left by her mother, with another child, while she went to work, in a room with a fire, when by some accident her clothes ignited, occasioning a burn, which on her admission was found to occupy the greater part of the upper arm, the axilla, and a considerable portion of the back part of the body on the left side. On these parts the skin had been completely destroyed, but in other parts, as in the forearm of the same side, the injury had not been so severe, the integument not being actually disorganized, although intensely reddened and inflamed by the action of the fire. On the hand there were several large vesications filled with a transparent fluid, which had collected before I saw her. She suffered intense pain, especially in the inflamed portion of the skin of the forearm and hand, where it had not been destroyed; the parts that were actually destroyed were, as is usual, not so painful. Lint soaked in the warm mixture of treacle and water was applied over the whole of the injured surface, with the effect of almost immediately relieving the pain, and appearing to put a stop to any further extension of the inflammation beyond what had been originally occasioned by the burn. The internal treatment was precisely the same as in the last case, with the exception that no other opiate was necessary besides the syrup of poppies, and that she took small doses of castor oil more frequently.

The effect of the external application in this instance appeared to be, as in other similar cases, slightly stimulating at first, but afterwards of a decidedly sedative character, it also seemed to possess the power of checking or preventing the putrefactive decomposition which often takes place in these cases, rendering the patient very offensive to the other inmates of the hospital; for instead of softening and sloughing, and coming away in putrefied masses with the dressings, as it usually does, the skin became hard, black, and shrivelled, gradually separating from the surface of the granulations at the margin by a kind of exfoliation, until, at the end of a fortnight the whole of it had been removed. She was discharged March 23, 1847, the wound in the axilla not having completely healed, with a very slight disposition to contraction, which, owing to the peculiar situation of the burnt wound, although it seemed to moderate it a little, the remedy was not capable of preventing.

CASE III.—Charlotte L., aged six years, ad-

mitted Dec. 31, 1846. From the same cause as in the last case, her clothes had caught fire, occasioning a burn, which occupied a large space on the upper part of the back, on the left side, extending into the axilla and for some distance down the upper arm; over the whole of the burnt surface the skin had been destroyed, as well as the cellular membrane underneath, and had the soft quaggy feel of complete disorganization. There was no difference in the intensity of the burn in any part, the integument having been destroyed wherever it had been touched by the fire. Owing to the complete destruction of this part, she did not seem to suffer any considerable pain, but, as she had only partially recovered from a protracted typhus fever, was a very unfavourable subject for so severe an accident. She had a feverish appearance, and complained of some slight pain in the bowels, but had no rigors. The same external remedy was applied as in the last case, but with a larger proportion of treacle, as the parts were not particularly painful. Internally she took syrup of poppies two or three times daily, with occasional doses of castor oil. At the end of a fortnight the whole of the destroyed integument had separated from the granulating surface underneath, having become previously converted into a dry and dark brown substance, which was removed as it became separated at its edges, by cutting it off with scissors, to allow of the application of the cerate dressing to the granulations, when the treacle could no longer be of service. The denuded surface suppurated freely, so that, as well as from her previously enfeebled condition, it was found necessary to support her strength, by giving her port wine and tonic medicines; but at the date of her discharge, March 23, 1847, the wounds had nearly healed, and as far as I could judge, notwithstanding their unfavourable situation, with but little danger of contraction. She had also recovered from the debilitating effects of the fever, from which she had suffered prior to the accident.

OBSERVATIONS.—The foregoing cases are only a few of those which have been treated, under my observation, in the manner I have detailed; many have been slighter instances of injury, and several as, or more, severe; but in all of them the beneficial effects of the remedy were more or less perceptible. Of course in some the parts had been so extensively destroyed that there was from the first no prospect of recovery; but, even under these untoward circumstances, I have fancied that the means I have employed have lightened the patient's sufferings and prolonged the fatal termination.

The action of the remedy appears to be directly sedative, and, as far as I have been able to observe, its first effects have been to lull the pain and moderate the inflammation which almost always exists in the integument surrounding parts which have been recently destroyed by fire, and which has a tendency to a destructive progress if no effective means are used to prevent it; that this also applies to deeper-seated tissues, and is a frequent cause of the fatal termination of such cases, is substantiated by the observation of Mr. S. Cooper, who, in reference to this subject, remarks:—

The extent of the mischief is often difficult to judge of directly after the accident, notwithstanding the characters of the various degrees of organic injury are strongly marked: for, at the same time that the heat disorganizes the parts on which it acts with the greatest violence, it always affects the textures immediately below them; and, though they may not be killed in the first instance, they may not be capable of bearing the subsequent inflammation, and afterwards mortify. Whether the remedy is capable of exercising the same beneficial influence upon these deeper-seated tissues, as it appears to do on the more superficial ones, I cannot for certain say: for, until the separation of the skin, they are not exposed to view; but, to the best of my judgment, it does so, moderating the inflammation here in the same manner as it does in the integument.

Its next most obvious effect appears to be that of modifying the tendency to putrefactive decomposition, which destroyed parts are prone to undergo prior to their separation as sloughs; and that it is capable of exercising such an influence I have scarcely any doubt, having had repeated opportunities of observing it, especially in the cases I have related, where its action in this respect was very remarkable; nor could the least putrescent or unpleasant odour be perceived during the whole period of the treatment. I had an excellent opportunity also of observing this latter circumstance in a case which, through the liberality of one of my colleagues, was placed under my hands for treatment. Although no less than 270 superficial inches of integument (principally of that covering the abdomen) had been destroyed, I could not, nor could those more immediately about the patient, at any time observe any unusual smell. I may mention that this patient lived a month, and at the time of her death the whole of the integument, having undergone the carbonizing changes observed in similar cases, had separated from the surface, which had begun to suppurate freely. On dissection there was no evidence of the duodenum or any other part of the intestines having been inflamed by metastasis, but she appeared to have sunk from the great suffering she had undergone, as well as from the shock, from which she had never recovered. There was a slight turgescence of the posterior part of the right lung, but whether from subsidence or other cause could not be accurately determined.

It remains only to endeavour to account for the smooth and regular cicatrization, which I have reason to believe is assisted by this method of treatment. It occurs, I think, in this way: the disorganized integument and cellular tissue, having undergone carbonization, remains adherent to the parts beneath, and while it is so in contact acts as an extraneous substance by excluding the air from the surface, and mechanically represses the growth of what would otherwise be exuberant granulations. As the carbonized integument is first observed to separate from the margins, the granulations round the periphery of the wound, by the contracting process which Dupuytren ascribes to the approximation of the margins to the central point, begin to cicatrize before the centre of the wound has become uncovered, which always happens last, and thus a gradual and even cicatrization follows.

It will also be observed, that what would otherwise be called the separation of a slough is prolonged by this treatment, until the system has recovered strength to furnish healthy granulations, in contradistinction to those irregular and unhealthy masses which are produced on a too early separation of the sloughs in a constitution yet suffering from shock, and aided in many cases by the stimulating applications which are sometimes employed. Perhaps, also, the constant application of the treacle dressing to the neighbouring skin, by rendering it more supple and extensible, may favour a more regular cicatrization, by enabling it more evenly to be drawn towards the margins of the cicatrizing wounds.

It is but right to mention that in the year 1838 Dr. Greenhow, of North Shields, published an account of the action of treacle alone, in excluding air from burnt surfaces, and in some way modifying the subsequent suppuration; but I was not aware of his having done so until some time after I had used it in a diluted form, and with different objects to those proposed.

OBITUARY.—On the 11th inst., at Fulham, Joseph Holmes, Esq., surgeon, aged 47.—On the 11th inst., at Bath, Joseph Channing Pearce, Esq., M.R.C.S., F.G.S., formerly surgeon at Bradford, Wilts, aged 35.—On Monday night, the 17th inst., at his residence, 308, Regent-street, universally beloved, John Philips Potter, assistant surgeon to University College Hospital, and assistant-demonstrator at University College.

MIDWIFERY.—SINGULAR CASE OF ABNORMAL OPENING IN THE ABDOMINAL PARIETES OF AN INFANT, WITH ESCAPE OF THE STOMACH AND INTESTINES.

Communicated by FRED. LOWES, Esq., of Gosport.

I was called at eight o'clock A.M., on the 8th of March, to a patient who stated that she had been in labour for three hours; the pains were of short duration, and occurring at long intervals. On examination I found the os uteri dilated to the size of half-a-crown, the membranes entire, and presentation natural. The labour progressed favourably, and she was delivered of a male child about half-past eleven A.M. On tying the umbilical cord I discovered in the bed a large quantity of intestine, which, on further examination, I found proceeded from an opening adjoining the umbilicus, but quite distinct from it, and receiving no covering (either of skin, fascia, or peritoneum). The mass consisted of nearly all the stomach, the whole of the small and large intestines, as far as the sigmoid flexure of the colon. I endeavoured to return a portion of the protruded viscera, but found it impossible to pass up more than the remaining portion of the

with croton oil on the region of the loins. Tartar emetic was also exhibited without procuring any relief.

On dissection a small quantity of transparent serum was found to exist in the peritoneum; the kidneys, otherwise healthy in their texture, were slightly injected on their surface; the lungs and heart presented no morbid change, and no alterations were detected in the brain or spinal cord.

M. Devorgne took occasion to remark that the fatal issue of this case was attributable in a great measure to the arrest of the cutaneous eruption. Instances of the kind were observed almost every year in hospital, and not only in eruptions attended with secretion, but also in others—*prurigo*, for instance—which it was often highly perilous to suppress, particularly in the aged. Whether the suppression resulted from too active a treatment, or from atmospheric causes—the influence of cold air, for instance, its effects were the same, and in asthmatic subjects death frequently occurred as a consequence of pulmonary irritation. In general, also, the anatomical changes noticed after death were not in harmony with the severity of the symptoms during life; abundant secretions in the bronchial tubes were, however, usually found, and might account for the permanent dyspnea which had previously existed.

Death of M. Lisfranc.—The celebrated surgeon of La Pitié died on the 12th of May from the progress of diphtheritic angina, complicated with pernicious fever, during the second paroxysm of which he expired. M. Lisfranc was only sixty years of age. The funeral took place on the 14th inst. It was most numerous attended, and MM. Pariset and Terres, and others, pronounced on the grave speeches expressive of their feelings on the melancholy occasion. As an operator, Lisfranc was unequalled, and it is a serious misfortune that his work on Operative Surgery, though far advanced, was not completed at the time of his death; his lectures, of the most practical nature, were always fully attended, and were remarkable at all times for the energy with which his opinions were expressed. Lisfranc has written few works: two volumes of clinical surgery, and an incomplete sketch of the art of operations; but in his books, as well as in his practice, the following principle is constantly illustrated:—"The operations of surgery are brilliant; but the art of the surgeon consists less in performing them with ability than in rendering them useless by proper treatment." Lisfranc's researches on cancer, on uterine disease, on white swellings, and his method for the partial amputation of the foot ensure to his name a place amongst those of the most distinguished surgeons of the French school.

D. M'CARTHY, D.M.P.

Habitual Miscarriage prevented by the Use of Antispasmodics.—Dr. Griffin, physician to the County of Limerick Infirmary, recommends to the notice of the profession the use of tonics and antispasmodics when there is an habitual tendency to abortion or miscarriage. In three cases, which he treated successfully, he employed the following remedies: two grains and a half of oxide of zinc, with two grains of extract of hop, three times a day; and, after each pill, two tablespoonfuls of a mixture of valerian, aromatic spirits of ammonia, and infusion of snake-root. He recommends also a box of pills to be kept by the patient, containing a grain of opium in each, to be taken when pain came on, and to repeat the dose every hour till relief is obtained.

Case of Double Amputation.—M. Brouzet relates the case of a man on whom he practised amputation of both legs below the knee, the one immediately after the other, on account of injuries inflicted by the wheel of a railway carriage. The patient suffered comparatively little from the double shock of the injury and the amputations, and made a speedy and perfect recovery.

Delirium Tremens.—Dr. Ware observes, that in cases of this disease, the patient, so far as the

paroxysm alone is concerned, should be left to the resources of his own system, particularly that no attempt should be made to force sleep by any of the remedies which are usually supposed to have that tendency; more particularly that this should not be attempted by the use of opium. This remedy he considers to be very seldom necessary.

Treatment of Enlarged Subcutaneous Bursa.—When matter is formed the only means is the evacuation of the fluid by a free opening; this is unattended with danger, and followed by a rapid and complete cure. When, however, the affection is recent, and the swelling does not yield to the application of blisters, or to the external use of iodine, if the swelling be not large, the best plan of treatment is to introduce a fine thread through it, and use it as a seton. On the second day this generally causes considerable pain, and requires withdrawal. A small quantity of puriform fluid passes for a few days, through the opening, after which the swelling gets gradually less, and contracting is completely cured.

General Erythema produced by Injury to the Membrana Tympani.—Dr. Cottman, of Whitehaven, United States, relates the case of a lady who, while picking her ear with a knitting needle, accidentally injured the membrana tympani. She immediately became insensible; pupils became very much dilated, face flushed, and tetanic twitchings of the muscles of the arm. This was succeeded by general syncope, which lasted for half an hour, when she became violently sick, and the extremities were cold. She continued in this state for five hours, when she fell asleep for a short time; afterwards she became sensible, complained of pain, and at times conversed incoherently. She was bled to the amount of a quart, with decided benefit, and in the afternoon two small blisters were applied behind the ears. Two days afterwards she complained of a roaring in the ears like distant thunder, accompanied with intense headache. In the afternoon she took eight grains of blue pill. After this she began to sleep well, the roaring gradually ceased, the bowels were gently opened with calomel and magnesia, and she speedily recovered without any defect of hearing.

Enterotomy.—Dr. Conger was called to a man who had received a stab in the abdomen with a large butcher's knife, near the anterior superior spinous process of the ileum, on the left side, cutting upwards to the extent of three or four inches. A large mass of intestines protruded, covered with coagulated blood, and there was profuse hemorrhage. The omentum was divided, leaving a strip five inches long hanging from it. The arch of the colon was severed at a point eight or ten inches from the cecum, at its lower edge, where the peritoneum doubles to form the mesentery, which was also slightly wounded. There was a puncture higher up, an inch in length. After tying four small arteries, the divided edges of the gut were brought into close apposition with sewing-silk by four interrupted sutures, the ends cut off close to the knots. The small wound was left, and the mass returned. The external wound was brought together with three interrupted sutures and adhesive strap, above which was a compress and bandage. He had a dose of forty drops of tinct. opii; the thighs were flexed on the body, and the legs supported with pillows under the knees. The patient at first was unable to pass his urine from loss of power over the abdominal muscles, and the catheter was used. At first there was restlessness, which was treated with T. opii. Tenderness required one bleeding to the amount of sixteen ounces. On the fifth day it was necessary to give an enema, the bowels not having been moved, which brought away hardened feces without pain. Afterwards the case went on favourably, and in a fortnight after the injury the patient was quite well.

White Swelling treated with Chimaphila Umbellata.—Dr. Blakey, of America, having under his care a youth of seventeen years of age, with a scrofulous white swelling of the knee-joint, which had been treated for a long time unsuc-

cessfully with iodine, blisters, and setons, gave a trial to the chimaphila umbellata, which was exhibited as an infusion twice a day; oatmeal poultices also being made with the infusion, and applied to the knee. Under this treatment the swelling gradually diminished, and eventually the knee (which was at first three times its natural size) became as strong as the one which had been unaffected.

The Blood in Cancerous Diseases.—Dr. Heller remarks that there is invariably in these diseases an absolute and relative increase in the amount of fibrine in the blood, and a considerable diminution in the quantity of blood corpuscles. In the large colourless cells which, by microscopical investigation, he discovered, and which formerly he regarded as true cancer-cells, he is now disposed to consider as merely the pale corpuscles of the blood, altered by the action of the water employed in the process necessary to demonstrate their existence.

Poisoning by Acetate of Morphia.—In the case of a person who had swallowed ten grains and three-quarters of this drug, and in whom tartar emetic had failed to produce vomiting, a highly concentrated solution of coffee with the solid residue was given, to the amount of ten ounces in twelve hours. Under this treatment the coma disappeared, and he perfectly recovered.

Division of the Vitellus in the entire Animal Series.—It is believed that among birds, scaly reptiles, and cartilaginous fishes, the organization of the blastoderm does not take place in the same manner as among other animals. The experiments of M. Coste prove that such a difference does not exist, but that nature proceeds in a manner identical in all cases. He has observed in birds, &c., during the passage of the ovum through the oviduct, the division of the vitellus to go on as in other cases, with this difference, instead of proceeding throughout the vitellus, it occurs exclusively in the cicatricula.

Diabetes and Dropsy.—Dr. Mackenzie mentions the case of a man with diabetes becoming suddenly affected with dropsy. As soon as symptoms of the latter disease made their appearance, the former entirely ceased, the urine was reduced to an ordinary or even less than ordinary quantity, and lost entirely its sweet taste. By means of diuretics the dropsy was removed, and that instant the diabetes returned. After a time, this latter disease again suddenly stopped, and the former returned, till at length the man died, worn out by these alternating diseases.

Bright's Disease.—Rimack confirms the views maintained by Henle, that the cylinders occurring in the urine are not modified urinary canals, but simply coagula of fibrine moulded in those canals. He conceives that the granular appearance of the cylinders is due to the presence of urate of ammonia. He regards their presence as of great importance in enabling to form an early diagnosis of the disease; and states that by this means alone, on several occasions, he has determined the nature of the disease several weeks before the first appearance of albumen in the urine.

The Urine in Scarlatina.—In cases of this disease the urine often continues to deposit a white flocculent sediment for a considerable time after the process of external desquamation has ceased. The deposit consists for the most part of epithelial scales from the surface of the bladder; and as long as it continues to occur the patient must be carefully watched, even though in all other respects his health be completely established.

Cancer of the Stomach.—A microscopic examination of the brown, chocolate-like masses observed in the sour vomited matters in cases of cancer of the stomach, has led to the interesting discovery, that they consist for the most part of yeast plants. In one case the fermentation was accompanied by a well-marked development of gas, and there was an obvious separation of the yeast into an upper and lower stratum.

Entrance of Air into Veins.—Dr. Wattman considers that the instantaneous and permanent closure of the wound of the vein is the remedy on which our sole and only dependence should

be placed. This might be done by compression whenever the lips of the wound can be completely closed, or when a flap or one of the lips of the wound can be laid over the vein and retained there. When this cannot be effected, either the vein must be included in a ligature, or, if there is but a small opening in a large trunk, the orifice must be pinched up in a small, light, spring forceps, and a ligature tied round the coats of the vessel included in the instrument.

Mercury in Yellow Fever.—This was once very favourite remedy in yellow fever, and it was considered that, at whatever stage of the disease salivation was excited, it was an infallible criterion of cessation of disease, and of returning health. Dr. Bone says, salivation neither cures nor prevents yellow fever; but, on the contrary by rendering the body more sensible to impressions from currents of cold air, *predisposes* to yellow fever.

Whooping-cough.—Dr. Bird has found alum most valuable remedy in the non-inflammatory stage, diminishing the secretion and relieving the cough. The following is the formula he has generally used for children of two or three years—*R.* Aluminis, gr. xxv.; ext. conii, gr. xij. syr. rhœad., 3ij.; aq. anethi, 3ij. m. ft. chchl., i.; med. 6ta quaque hora.

Fistula.—The treatment of fistula by stimulating injections, when they are so situated that they cannot be laid open, has been proved by Dr. Morand to be particularly advantageous. In the case of a young woman who had suffered for nearly twelve months from a fistulous opening in the right iliac fossa, after the ordinary means of treatment had failed, a solution of chloruret of soda was thrown in with the best effect, the fistula being firmly closed in a fortnight.

Syphilitic Eruptions.—Of all the mercurials which have been recommended in the treatment of syphilides M. Cazeauve has found none so efficient or valuable as the protoiodide of mercury. It seldom occasions salivation, and under its influence the patches of disease assume a more lively and healthy aspect, and evince a tendency to resolution. The general condition and appearance of the patient improves a remarkable alteration. The countenance becomes more animated, and the eruption advances towards resolution with a rapidity which, in some instances, is really surprising. It is worthy of note that when the administration of the protoiodide is likely to be followed by beneficial result, these latter will begin to appear in the course of a few days from the commencement of the treatment. In the mild forms, not of long standing, ten grains of protoiodide formed into twenty pills with liquorice powder are to be made. Dose to begin with one, to be increased to two, and afterwards to four pills in twenty-four hours. In the severe tubercular varieties two scruples are made into forty pills, and administered as the preceding.

Dysentery.—The fecal evacuations in dysentery and typhus ordinarily present similar appearances, yet, under the microscope, they occasionally present striking differences. In the former, crystals of ammoniaco-magnesian phosphate are very rare, and the blood corpuscles are not so much decoloured nor so modified in form; long strings of coagulated fibrine are intermingled with the corpuscles. The granular cells are mixed with numerous flattened, spherical, and cylindrical epithelial cells, and the whole are imbedded in the structureless stroma of the mucus. Conferva, and sometimes fermentation fungi, occur in great excess, apparently in direct ratio with the acidity of the evacuation.

Rupture of the Uterus.—M. Robiquet attended a woman in her confinement, when the uterus gave way spontaneously after twenty-four tedious but not severe labour, and no very grave symptoms succeeded the occurrence. After delivery, a portion of omentum and a coil of small intestine prolapsed at the vulva. Soon after their return, the uterus contracted well, and on the seventeenth day the patient was convalescent.

Ether-Vapour Enemata.—M. Pirogoff, of St. Petersburg, has been trying some experiments on the effects produced by the injection of ether vapour into the rectum. The ether is introduced by means of a catheter attached to a syringe, the latter being enclosed in a vessel of water sufficiently heated to convert the ether into vapour. The odour of the vapour was perceptible in the breath in from two to four minutes. The quantity of ether used has varied from half an ounce to two ounces. No injurious symptoms have followed its use, and the most troublesome operations have been performed with great facility.

Hydrophobia.—Experiments performed by Dr. Eckel have proved to his satisfaction that rabies is not transmitted at distances, nor by mediate or immediate contact of the bodies of animals, living or dead, but only by the bite of the rabid animal, or by inoculation.

Chemical Composition of Osteo-Sarcoma.—M. Roux analyzed a specimen from a tumour removed from the humerus. It consisted as follows:—

Water	87.86
Chlorine	0.85
Albumen	0.30
Margarine, stearine	0.28
Carbonate of lime	0.67
Phosphate of lime	0.59
Sulphate of soda and potash	0.28
Carbonate of soda	0.11
Sulphate of magnesia, silica, &c.	a trace

REVIEWS.

On Indigestion, and certain Bilious Disorders often connected with it. To which are added, Short Notes on Diet. By GEORGE C. CHILD, M.D. 8vo., pp. 219. London, 1846.

The subject of indigestion has been so often handled, and so well, by writers at home and abroad, as really to leave little room for novelty in treating it. At the same time, the accumulated observations of previous scribes make it somewhat easy for those who follow, and are welling to be satisfied with dressing up old facts in new clothes. A certain Welsh parson, not very competent at sermon-making (we should like to know any Welsh parson who was), used to buy his discourses, and, by way of disguising them, translated them first into Welsh, and then back again into English; after which transmutations he would have defied the very authors themselves to make out their own. Medical writers who work by borrowing of their predecessors do not go in so roundabout a way as this to make books, but dash along with scissors and paste, as though selection and appropriation constituted the sole business of authorship. A lucky fellow, once upon a time, possessed a cat which he could always make a dinner by when he was short of one. Sixpence was the price of this cat, for which sum he often sold her; but she always came home again, to give him fresh opportunities of merchandise whenever his pocket might happen to be low. We have often thought, if the original facts developed by authors would return to them like this cat, how many men would go empty-handed, who have managed to carry on a literary trade with the capital of other people.

We do not mean to charge this sin upon Dr. Child, for a moment, as an intentional transgression, for, if a man write upon a subject whereon nothing new is to be said, nothing new can reasonably be expected from him. We did not open the volume before us with the most distant idea of its containing any novelties: we knew the thing to be impossible; yet it is something to say that the sum total is composed of very decent materials derived from very decent sources. Dr. Child has obviously begun by reading and making notes from the chief authors in the subject of stomach and bowels, and has connected these various gatherings into one

mass, with intermediate material of his own. This he has obtained from some experience, very creditable to his industry; but still we cannot, even from the cases himself has treated, find anything that goes one step beyond our previous knowledge upon the popular subject of indigestion: and it appears pretty clear to us that, notwithstanding his experience, the impression of his reading is uppermost. Were the authors from whom he has derived aid all referred to with precision, the work would have greatly the appearance of a graduation thesis. Occasionally, however, throughout the work, there are straggling inaccuracies, which we are surprised to see, considering that it is for the most part a compilation.

At page 17 we are told that "the stomach may be viewed as a hollow muscle, or gizzard, where mastication is finished." We humbly think that this view is somewhat the reverse of right. We have yet to learn that the stomach is either a muscle or a gizzard, or that it can perform the feat of mastication.

At page 19 we learn that "urinary calculi consist essentially of earthy particles," held together by a cement of animal matter." What essential earthy particles are there in the most common of these, the uric-acid calculus?

At page 23 he says that physiologists are by no means agreed as to the use of the saliva. It has always been our opinion that physiologists are pretty well settled upon this point.

"It has often occurred to me, that one use of the saliva may be, by means of the air it contains, to keep the morsel porous, and readily permeable to the gastric juice." Is this sin against pneumatics and physiology serious? Dr. Child really could not have meant what he wrote.

"The effect of morbid changes in the saliva upon digestion is not known." We had imagined, in our simplicity, that these were known tolerably well. If Dr. Child will turn to the *Lancet* of 1841-42, he will find that a certain author named Dr. Wright has classified the varieties of morbid saliva, given their distinctive physical and chemical characteristics; and furnished many cases, from his own practice and that of others, of indigestion being secondary of a depraved salivary secretion. In such cases it is advised by the author referred to that stimulating gargurisms shall be used; and that in very bad cases the offensive saliva shall not be swallowed. He will find also, in the same numbers of the periodical, an astringent wash for the mouth, in salivary discharge symptomatic of dyspepsia, recommended by the same author, which he (Dr. Child) prescribes at pp 139 and 140 of his work, as though the suggestion were now made for the first time. We cannot help thinking that our author has not been accidental in his prescription here, for at the time of Dr. Wright's papers appearing this form of practice, in these particular cases, was quoted by journalists on account of its novelty.

According to Dr. Child, the manner in which dyspepsia becomes intricate may be illustrated by the following plan:—

1st. Starting-point: simple indigestion in a person otherwise sound.

2d. Complication. Indigestion in a person of scrofulous constitution.

3rd. Indigestion in a scrofulous person exhausted by a weakening discharge, or by nursing.

4th. Indigestion complicated with scrofulous diathesis and exhaustion from nursing; also with some local complaint, as chronic bronchitis, or uterine disorder.

5th. Arising from the addition of erythematous inflammation to the above." (P. 43.)

What the "starting-point," here, has to do with the illustrations underneath it, we cannot exactly see. We cannot for a moment admit the latter to be varieties of the former, or complications of it, as our author says. These he makes it appear are particular states of health in which dyspepsia is apt to occur. But, in arranging these as varieties under the first proposition, what other is it than saying, that the

"scrofulous diathesis or constitution" is a "complication" of a "sound" one? Again, surely Dr Child does not mean to say that indigestion only occurs in five forms—in a subject otherwise healthy, in a scrofulous one, in one scrofulous and weakened by some cause, in another of this sort, troubled additionally with some local disorder; and in any one of these with erythematous inflammation added? According to this, a man must either be in good health (his stomach excepted) when he is dyspeptic; or he must be scrofulous. Has Dr Child never seen indigestion unconnected either with general good health, or with the scrofulous diathesis or constitution? We have often.

At page 60 we are informed that, "in the liver, the carbon is excreted along with the bile." This is very much like saying that in the operation of phlebotomy the blood corpuscles escape along with the blood. We should not have mentioned this error, but it does not happen to stand alone.

A favourite remedy of our author for unloading the liver consists of six grains of calomel, ten grains of compound extract of colocynth, half a drachm of compound jalap powder, and ten grains of sulphate of magnesia (p. 127). The *monium* he advises to be given, when it does not produce sickness, for several days in succession. We should really think such a dose would not need a repetition very often.

The chapter on Pyrosis is very creditable to the author's industry, but we cannot help thinking that a good deal of it is due to West's "Treatise on Water-brash," though, strangely enough, Dr West's name is nowhere mentioned. It may have happened that Dr Child never saw this work, which made its appearance in 1841, but his own production certainly very much resembles it.

In describing the ejected fluids of pyrosis, at p. 185, our author forgets the most common variety—that which is as transparent as water, of scarcely higher specific gravity than thus, and containing scarcely anything but a little chloride of sodium.

At p. 137 Dr. Child says, "The hydrochloric acid is for the most part derived directly from the food,"—we suppose he means from the common salt contained in the food. But does he not know that the experiment has often been tried, of feeding animals, and even man himself, with food containing no salt, without there being any lack of hydrochloric acid in the gastric juice, in consequence?

At p. 186 we learn that "the gastric juice seems never to be secreted in excess." We rather opine that there are some cases on record, of solution of the stomach, which prove the direct contrary.

At p. 149 Dr. Child talks of pyalism in dyspepsia, and calls it "false pyrosis." As well might he call bronchitis a false phthisis. Pyalism is pyalism and pyrosis is pyrosis, and they in nowise relate to each other, except in so far as according to Dr Wright, whose opinion was founded upon an analysis of the ejected fluid, the matter of pyrosis is secreted in saliva that had been swallowed. He further calls this pyalism a symptom. It is only often an idiopathic affection.

At p. 177 we read that the "presence of bile-pigment in the urine may be more accurately ascertained by the addition of nitric acid, by which the colour is changed successively from green to violet, red, and yellow." A very extraordinary change of colour, and, we should say, in the first place, the natural purplish yellow, with, at most, only a faint shade of green. The addition of an acid such as nitric or muratic, to it, deepens the green tinge, which afterwards passes into an olive and finally almost into black. Such an undeviating order of colouration is a chemical peculiarity we have never yet seen.

We have read Dr Child's book at random, and have found the above-mentioned faults in it, of which, as impartial reviewers, we have felt it our

duty to speak. We have spoken the more plainly, because we expect, if we were to read the work through with the express object of criticism we should find its errors much more numerous.

Nevertheless, it is a very creditable production, and is for the most part plainly and correctly written. It contains nothing new, and something that, scientifically speaking, is not true, yet, with all its faults, it is calculated to prove of use, by conveying intelligible information, in very fair quantity, upon the subject of dyspepsia.

The Surgeon's Vade-Mecum. By ROBERT DRUIT, M.R.S. 11th Edit. Renshaw, Churchill 1857.

Celebrity is not always confined to originality, and a man, when he resolves to become an author, may obtain honourable fame by judiciously selecting and condensing the truths which others have made known to the world. It is no easy task to collect from the best sources scientific information, and arrange it in such a manner that the book may be carried easily in the pocket and be made interesting and useful companion. Most manuals and vade-mecums are very trivial productions, and a badly become voluminous waste paper. This press is ever active, and it is attractive to writers as the empy to moths, and it is to be content very frequently proves as destructive to the delicate wings of the one genus as of the other. Mr Druit, however, is an author of a superior class, and his book is justly held in estimation by the professional world. The work has now reached its fourth edition, and its pages are enriched with the fresh valuable information suggested by the advance of surgical knowledge. The author has mentioned in his preface the departments of the book which have received the greatest improvements, and he has not thought it beneath his duty to add an entirely new chapter on the art of bandaging, with copious illustrations, drawn from nature under his own superintendence. To the surgeon this may appear a work of supererogation, but it will be appreciated by an extensive class of readers, the *tyros* of the profession. True it is that bandaging is an art which can only be dexterously accomplished by practice, and a surgeon's reputation will often rise and fall by it. Yet few directions from an experienced hand are good helps to those who are not at fault in the matter. The number of wood engravings have also been augmented, and are well executed. All the editions have been highly meritorious, this, however, is by far the best of them. The work needs and can, indeed, be no higher praise.

TO CORRESPONDENTS

THE MEDICAL TIMES may be procured by an order on any Newsman or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein & Co., or an order on some party in town. One Guinea IN ADVANCE, which will free them for twelve months. Half yearly Subscription, 13s. Quarterly, 6s. 6d.

But let us go off with too much report the change is a little too heavy.

A Birmingham Student has mentioned the making of the article. There is no originality in the article, it is merely a collection of a number of facts, and a complete and being so simple, it is worthy of general diffusion. The fact that the oldest clinical professor at Queen's Hospital, Dr Wright, using it so frequently, and detecting by the presence of sugar in the brain of a man who had died of diabetes, is at once a proof of its value as an argument for its publicity.

Mr William Fraser, Dublin.—The request will be attended to.

A Student, Pine Street School of Medicine, Manchester.—We are sorry there should be any differences between Mr Smith, the demonstrator,

and his pupils, concerning the money paid for subjects, and we hope matters will be amicably arranged.

Students must remember, in reference to the distribution of prizes, that it is possible for a young man at one time to be "morally bad in his conduct," and afterwards to be so reformed as to be worthy of a certificate of honour "for good moral conduct."

Mr Jebb.—The penal clause in the Registration Bill offers far less security against illegal practitioners than that in the Apothecaries' Act of 1816, which is working well, with the new interpretation put upon it. The Company, we believe, will not be easily plucked by certain noisy politicians.

Mr J Jones, Llanfair, Montgomeryshire.—The suggestions will receive our consideration. The questions are so many that it would take a long column to answer them all. A work on Chemistry well suited for those whose knowledge is defective as regards this science is "Kane's Elements."

Chirurgus, Derby, does not appear to clearly understand the subject. A carrier with plenty of capacity but lacking return, is easily conquered. The College possesses a charter, but not an act of Parliament. There is a right to any barber or hairdresser to perform operations on the face and head of a patient, but the College could not have the power to prevent this practice.

Sam Sack, Worcester.—The party was invited to a dinner, but we cannot say who the supper was that the supper is so freely as to give such a help to the cause that it is perpetually in the air. The party themselves will afford the desired information, if not, on application.

Archie, Berwick.—The provincial schools of medicine are now opened by the Hall and College of Medicine, and the Medical Times Almanac.

A Bachelor, London.—We are aware of the truth, but cannot obtain signatures. Plenty of payment for names will not be found to answer the purpose intended.

Mr Deane, Northampton.—Qualified practitioners must sign the certificate. A double qualification is not necessary.

He must had better write to the Editors of the Pharmaceutical Times, who will afford him the desired information.

Mr James.—The letter is at our office, which may be obtained on application.

James.—We published some time ago Dr. Corrigan's lecture "On School" in the *Theory and Practice of Medicine*.

J M I., Lewkesbury.—The acetum lytta, when good, is an efficient and powerful blistering agent.

Austicus.—The tincture of uric acid has been applied to smallpox pustules to prevent "pitting" with some success.

F Henley, M.D.—There are medical men in Egypt who have a scientific knowledge of their profession. We agree with our correspondent "that whoever he was that first suggested to the Pasha the idea of turning mummy linen into gold must have been a very shrewd fellow."

A Country Practitioner.—The inhalations are still successfully used in the London hospitals when capital operations are performed. There seems no danger, at present, of its being "ultimately laid aside" either as inefficient or injurious.

Philo, Liverpool.—The paper is under consideration, and may, at some future time, be admissible.

A Friend to the Insane.—The commissioners in vacancy will investigate the matter. The statement but better not be published at present.

A. A. Z. Esq.

Mr W J Anderson will have a communication in next issue.

P S M R C S I.—An M.D. who has received his diploma from the University of Edinburgh, or any of the Scotch Universities, may practise in England without registration.

Mr B W Brown, Wincoburn, Leicestershire.—The case of strangulated inguinal hernia, with operation, has been received.

Mr. Robt Wm Ellis will see that we have attended to his request.

Mr. Geo Millett Davis, Liverpool.—The communication has been received, which will be noticed next week.

We have also received communications and letters from Mr. Wm Smith, Belfast, Mr. Evans, Poulton, North Wales, Legend, A. M., Lambeth, Mr. Lewis, Gosport, (Chirurgus), Mr. Wm. Frazer, Arron-quay, Dublin; A Student, Queen's College, Birmingham, Mr. Jones, Llanfair, Mr. George Higgins, Manchester, Amicus, Philo, Dr. Henley, A Reformer, Mr. Deane, Mr. Jaggow, Mr. A. Benson, Brompton, Mr. Lillie, Colston's parade, Bristol, Mr. Epton, Southampton, Mr. Haide, Chilton-on-Medlock, Mr. Oldham, Brighton, Mr. Williams, Ancoats, Mr. Haldbrook, Cheltenham, Dr. McGregor, Glasgow, Mr. Whitehead, St. Alban's, Mr. Hurdwicz, Rompall, Dr. Woods, Parnassus, Mr. Drummond, Brighton, Dr. Tyke, Aberdeen, Mr. Martin, St. Columb, Mr. Lookes, Stallbridge, Mr. Watt, Southampton, Mr. Sampson, Southampton, Dr. Ellis, Dublin, Dr. Shelly, Cork, Dr. O'Connell, Dublin, Dr. Sower, Coleraine, Mr. Connolly, Killeagh, Mr. Bosquet, Stapleford, Mr. Fry, Walsby, Mr. Taylor, Baltimore, Dr. Carmichael, Buchu, Mr. J. J. Anthol, Mr. Malvern, Lincoln, Mr. Albutt, Batby, Mr. Sweeney, Clonmel, Mr. Irvine, Morville, Dr. Mathews, Donough, Mr. Howard, Linton, Mr. Hallett, Latham.

THE MEDICAL TIMES.

SATURDAY, MAY 22, 1847

PUBLIC JUSTICE AND MEDICAL CORONERS

When a public jury is done to the admiration of the public, and a severe hardship to one or more of the subjects, it is of the first importance that we should not suffer either on either side of the temper to allow the officer to go without punishment. The maintenance of a good system of social relations depends upon a watchful and over this principle, and if ever great and wanton aggressions should be committed, are tried, and delivered to condign punishment, it is especially so where the offender holds a conspicuous position, commits his delinquencies in the public eye, and is surrounded by circumstances which seem to assure him, with the rewards of meddling, permanent impunity and temporary triumph. As social good is injured by individual efforts, so also is it maintained and vindicated, and the careless, apathetic, good tempered multitude must be ever indebted for a good system of social administration to the exertions of individuals either loving justice more ardently or asserting it more energetically.

Under one aspect the melancholy of the Hounslow Inquest might be allowed to be quickly enshrouded under the curtain of public contumely which has of late been drawn over it. The great performer in the scene, after perusing everything, to secure a great personal triumph, has, if he has not met his deserts, at least utterly and wholly failed in the object he proposed for himself.

His political position has not been improved. The public sympathy excited has not been secured. The great things that were to make a political celebrity out of a partial judge have not been held, and that handsome testimonial which was to have added so largely to the *resound* has never risen above what would hardly look respectable even as a supererogatory. Between the gigantic unprincipledness of a partisan magistrate and huge political success there stood the *Medical Times*, and the *Medical Times* alone, and while justice has been baffled, right, if not fully vindicated, has at least not been permanently hurt. It is neither right, however, for the public, for the profession, for the cause of justice, nor for our

own consistency that matters should rest here. There must not be one iniquity in the whole series of iniquities hidden from public notice and condemnation. It would be worse than wrong—*conard*—if we suffered such a man, after such acts, longer to defile the judicial seat. Courts of justice must be moved, the House of Commons agitated, and no rest given till a severe retribution be won. The first great fact that is by this time everywhere known—the judicial suppression of the testimony of two most competent witnesses—must not escape a speedy investigation, and to this end we now proceed to detail the circumstances of a transaction unparalleled, we believe, in the annals of our courts of justice.

The inquest was held on the 14th of June, 1846, the poor man White was supposed, in the neighbourhood of Hounslow, to have died from the effects of flogging, but on no better authority than the motley and unimpressive rumour. That the officers had been guilty of any extra severity was not charged, the *system* of flogging itself was imputed the percent cause. Under these circumstances a coroner would naturally feel no more than inclination for personal specimens of *accusations*. He would, if fair, prejudice nobody and be open to all candid and authoritative evidence. With this conviction on the mind of Colonel Lytton, and believing, no doubt, that there was nothing in the transaction that would justify the fullest scrutiny, and that the result would conclusively remove the foolish as well as unjust, rumours circulated about, he charged the officer of the regiment, who knew more about the history of the matter than any other man in the regiment, to attend the inquest, and give all the information within his power. Captain Shirley, now the colonel of the regiment, was the captain to whose troop poor White was attached, he was the president of the court martial by which this private had been tried and sentenced, he was present at the infliction of the punishment, and further, had visited the patient twice or more in the hospital after the flogging, and before his death. It was impossible to fix on a person with more information, and, from his position, one on whose testimony more confidence could be placed. Captain Shirley attends the inquest, and, after stating that he is commissioned to give the coroner every facility for the inquiry that the regiment could afford, and every information in his power for its elucidation, he is accepted as a witness. The deputy coroner, in the presence of the public, examines him on every circumstance of the transaction, and in evidence the statement is written down as dictated by this functionary, who, not content with this summary narrative of the witness, cross-examines him on many of the events, recording every answer dictated. At the termination of this examination the coroner again questions him on every point in viewing the body the deputy coroner tells Captain Shirley that the evidence is satisfactory as far as it goes, that he must be sworn to its contents, and that he must hold himself in readiness to answer any questions which the coroner may further wish to put to him.

Captain Shirley tells us that the evidence he had thus given was most material, that it completely exonerated the officers from any imputations of inhumanity, iniquity, or ill doing, that it consisted of facts which, if published, would have removed every unfavourable impression as to the cause of the poor man's death, and he further vouches that he held himself

in readiness to bear any other examination, and was at all times in readiness to be sworn to the facts he had deposed.

Now, what is the startling fact? Captain Shirley, though further examined by the coroner, as promised, was never sworn to his evidence, and that evidence was never submitted to the jury. But the suppression did not stop here: the deputy coroner, noticing, no doubt, the direct tendency of such conclusive testimony to strip the judicial procedure of its dramatic importance, would appear to have thought that the contrasting evidence of a private soldier would not be without its value, and, therefore, he calls forward from the crowd about the inquest-room one of the band of the regiment who had been present at the punishment. Private Rising, however, being a person of honest and good character in the regiment, neither thinking nor dreaming of turning any public excitement to profitable account, and having yet no speculation that "stunning" evidence would purchase him his discharge and win him popular notoriety, stated impartially what he knew, what he had seen, and what he had observed, and his testimony was, of course, confirmatory of that of the honourable and upright officer who had preceded him. Examination and cross-examination were duly recorded by the deputy coroner, the man was to hold himself in readiness to be sworn and further examined, he did so hold himself in readiness, but he was never sworn, and his testimony never was submitted to the jury. It was SUPPRESSED. But we have not done with the suppression here. There was one reporter present, and only one. That reporter—a gentleman favourably known to his profession—was appealed to directly by the coroner during the proceedings, and his presence was not only required, but sanctioned.

Did that gentleman report the evidence of Captain Shirley and Private Rising? He did. Did that suppressed evidence, then, appear in the papers? No. Why did it not?—A few facts will explain. Mr. Teuten, having written his report of the proceedings, including the testimony of Captain Shirley and Private Rising, had prepared copies for all the morning journals. But it was convenient to suppress that material testimony from the jury, it was still more important to exclude it from the public. What then happened? Mr. Christopher Teuten, of Soarsdale-terrace, Kensington, was invited to take his place in the carriage of the two coroners, who had proceeded through Kensington on their return home. Did they drop Mr. Teuten at Kensington? No. They took him to Bedford-square, and at midnight, Mr. Teuten, instead of sending round his reports to the morning papers, sends, to the *Times* alone, a new version of the story, written since his arrival in town—a version which is headed "Death by Flogging," which omits all reference to the testimony of Captain Shirley and Private Rising, and makes the whole affair to assume characteristics so mysterious and tragical as could not have failed to cause a most intense and general public excitement. Why did Mr. Teuten abandon his reports written fairly, at the time of the inquest, under no dictation? Why did he give up so many copies that had caused him so much trouble to prepare? Why did he relinquish the large remuneration which so interesting a report in so many journals would have been certain to secure him? Why did he limit to the *Times* a brief report so contrary to everything deposed to by the only two witnesses examined in the transaction? Let Mr.

Wakley, whose house he left on the midnight of that day, answer these questions if he can! Let those functionaries respond who suppressed the same evidence to the jury!

These are questions that will be conceived to demand an answer; and, in the hope that we may hear something in explication of them, we postpone further observations on this most extraordinary case until our next number.

THE CASE OF ILL TREATMENT AND DEATH OF A PAUPER LUNATIC AT GROVE-HALL, BOW.

THE trial of the two keepers for the manslaughter of a pauper lunatic in the above establishment came on last Thursday, before Mr. Justice Alderson, at the Central Criminal Court; and we cannot allow it to pass without making a few remarks upon the facts which have been elicited. The prosecution of the criminals was at the instance of the Commissioners of Lunacy, and, had it not been for their watchful superintendence, it is highly probable that these inhuman keepers would never have stood at the bar in the humiliating condition of culprits, but would have been still pursuing their calling with that old-fashioned despotism which terrified unfortunate maniacs into submission by the infliction of blows, or the application of strait waistcoats. Even now, with Government officers to inspect these establishments, the guilty men were within a very little of escaping detection, for, though death followed their cruelty, the medical officer of the asylum, when examined before the coroner, gave it as his opinion that "death arose from disease of the heart, with serous effusion into the chest," and consequently a verdict to this effect had been recorded. It is singular that such an opinion was hazarded, and that a *post-mortem* examination in the first instance was not made, because there was sufficient proof, from the wounds and bruises of the sufferer, that violence had been used towards him, and which certainly did not escape the notice of his medical attendant. Better far that the autopsy had been speedily performed, than that it should have been afterwards forced by those murmurs without, which were not only heard within the walls of the asylum, but afterwards reached even the ears of the Government commissioners. Better, we say—especially for the medical superintendent, because he would not then have been under the painful necessity of coming forward to state that he had discovered five ribs broken by violence, one of which had penetrated the pleura, and that this was the cause of death—not "disease of the heart, with serous effusion into the chest." The public are now very suspicious of the conduct of all officers in private lunatic asylums, and such occurrences as these serve especially to bring medical evidences into disrepute, when coming from one who is supposed to be an interested party. The *Times*, therefore, very sagaciously remarks, "The contradiction between these two statements, both proceeding from the lips of the same medical man, is indeed remarkable;" and then ironically adds, "We cannot, however, find fault with the mistake he made in the evidence he gave in the first instance, for he had no opportunity of ascertaining the facts which a *post-mortem* examination alone could have discovered." If those who have the management of this establishment had been properly alive to their own respectable standing with the public, they would have been more forward in using every means that suspicion might be averted from them. Surely one of their pauper inmates could

not have been beaten, kicked, and knelt upon without their knowledge. When patients are placed under their care they are not to be left to the tender mercies of servants, whose only qualification for their duties may be physical strength, with but little kindly feeling to control its exercise. Hence, it was the imperative duty of the principals of Grove-hall to have at once instituted such a searching investigation into Blank's death that would have satisfied the poor man's friends, the Government, and the public. There was a tardiness, however, from some cause, and the consequence is that there is an unfavourable feeling towards the establishment and its officers, which might, perhaps, have been easily prevented.

And here we are reminded of the very trying situation in which a medical witness is placed when called to give evidence in a court of justice, where powerful causes may be in operation to bias his testimony. A high moral feeling alone can help him honourably through his difficulties; and we do not mean to say that in the present instance those feelings were not in exercise. Far better would it have been, however, if a professional gentleman had been placed in the witness-box, unconnected with the affair, and whose motives, in consequence, would have had no chance of misconstruction. Hence we view the sentiment as correct which has been enunciated by the press, that "the medical officer, who may be compromised by the result of an inquest, should never be the *only* person to give evidence of the way in which death has been occasioned." Nay, more: we consider the carrying out of such a principle to be one of the surest means of securing for the members of the profession the greatest approbation and confidence of the public.

The manner by which this unfortunate maniac came by his death is a proof that something more is yet necessary to ensure the efficient and humane treatment of paupers in private asylums. It is frightful to contemplate the increase in the number of incurable lunatics in places set apart for their reception; and who can wonder that the most beautiful features of the mind are for ever obliterated, if poor sufferers are doomed occasionally to experience the despotic power of servants, which they will be ever ready to dispute, either in fear or in danger? There must be a still closer inspection of these places, in order that no inhuman keepers may be found exercising their vocation to the injury of the patients: no, not if they should, in any of their paroxysms, commit acts of violence. If this man had not died, should we have ever heard of his blackened eye, his fractured ribs, his bruised body, and the bloody stream issuing from his mouth? What men have we here, who, while one is inflicting blows with merciless severity, another can urge him on by calling out—"Serve out the old devil;" while a third, beholding the terrible scene, comes not to the rescue of the sufferer, but merely says "Drop it"! Were they, for these brutal acts, immediately expelled from their situations as unmerciful servants? It seems, by a subsequent statement of the medical officer, that one was dismissed and the other two placed under short notice to leave, before the official investigation commenced; if this, however, had been done before the man expired, it would have removed those suspicions now entertained, that it was only the prospect of a searching investigation that prompted to the act.

But what said the Judge in reference to the

conduct of the prisoners when placed in the dock? In answering as he observed, "that the keepers of this asylum had a perfect right to make use of any reasonable violence that might be necessary to restrain their patients; and if violence, therefore, was made use of, it was not necessarily illegal." Reasonable violence! What is that? Baron Alderson may consider it one thing, and men of the same stamp as the prisoners at the bar another; hence we see the necessity of a sharp watch being kept over the conduct of those who on certain occasions might be inclined so to interpret the learned baron's doctrine, as to use measures which they might consider reasonable, but which disinterested spectators might call cruelty or vindictiveness. Men, in the right discharge of their duties, ought certainly to be protected; but no amount of violence on the part of a maniac, that we know of, could justify those who have the charge of him crushing his ribs, so that the splintered bone pierces the lining membrane of the chest, and death ensues.

The trial, conviction, and punishment of these individuals will not fail of producing salutary effects: the public eye will be directed more constantly to lunatic asylums; the managers of these places will be more anxious to employ servants with moral as well as physical endowments suited to their office; while the keepers, more careful in the discharge of their functions, will not expose themselves to the danger of three or six months' imprisonment by manslaughtering an unfortunate patient who may be occasionally obstreperous.

THE PHARMACEUTICAL BILL.

THIS bill, now before the House of Commons, is exciting a good deal of attention throughout the country; and we, therefore, present to the members of our profession a brief outline of it, intended as it is for the renovation and elevation of that community for whom it proposes to legislate.

It commences with the declaration that it is expedient for persons exercising the business of pharmaceutical chemists to be acquainted with the Latin language, and other branches of useful learning; that the Pharmaceutical Society shall have the power, within one month after the passing of the bill, to appoint a registrar, who may be removed at any time by the council, and another appointed in his place.

All persons members of the Pharmaceutical Society when the act is passed, and every person who shall within one year present a certificate, signed by two magistrates, that he was engaged in the business of a chemist and druggist, to be registered without fee.

The council to publish annually a list of persons registered. The Board of Examiners appointed by the society to conduct the examination of candidates; the board to consist of two professors of Chemistry, Pharmacy, or Materia Medica; and not less than four or more than eight members of the Pharmaceutical Society to be annually appointed.

The council of the society to be empowered to make and alter by-laws, which are to be approved and confirmed by the Secretary of State.

The certificate granted by the society to entitle the possessor to engage in the business of chemist, &c., and for this certificate he is to pay five guineas. All registered persons to be eligible for election as members of the society.

That after the act, no person is to be registered but such as have been examined.

Every person, not registered, who shall use the name of a chemist, &c., is to be fined, which can be imposed by a magistrate upon the testimony of a witness—one half of which to be paid to the informer, and the other half to the Treasurer of the Pharmaceutical Society.

A person obtaining a fraudulent certificate to be fined.

The act not to affect certain privileged bodies, professional persons, manufacturing chemists, or wholesale druggists.

We think that this bill will not be satisfactory to the druggists, and we are quite certain that it will not be to the medical profession.

THE BILL AND THE CHARTER.

TO THE GENERAL PRACTITIONERS OF MEDICINE, &c.

GENTLEMEN,—The enemy of the peace and welfare of the profession has again endeavoured to set us at variance, and to break up that great organization which alone can accomplish our redemption. He may strenuously labour to this end; but he cannot succeed if we are honest to ourselves, and true to the fundamental principles which brought us together. If the profession are to be deluded by impracticable promises, sneered out of their consistency, and bullied into submission to the despotic will of a vain and self-seeking agitator, then let us abandon at once the league and fellowship we have hitherto gloried to call ours; let us confess the imbecility of all our attempts, the hopelessness of our aims, the falsity of our principles, and let us resign to others a triumph which we are unable and unworthy to achieve.

Is it because an individual, impelled by an insane vanity, and with an utter recklessness of the result, may choose to undertake a scheme of Medical Reform, and promise us benefits which never can be derived from its operation, that, therefore, we are to confide our judgment to his keeping, and wantonly support what our worst enemy as wantonly proposes? Are you, gentlemen, content to be divided, now, for your vacillation, and to be punished, hereafter, by its disastrous consequences? Are you so blind that even a dog may lead you whithersoever he will—so infatuated that you can surrender the honour of your profession to the guardianship of a profligate politician, and so insensible to your true interests that you are prepared to sanction measures that will compass your probable ruin? I hope not.

I have considered this Registration Bill thoroughly: all its bearings, present and ultimate, have occupied my closest attention; and I am constrained positively to assert that a more dangerous measure was never attempted to be foisted on public credulity. I may add, also, that infamy was never more plausibly covered. The hypocrisy of the scheme is only exceeded by its wickedness.

What, gentlemen, was the grand principle that electrified professional sympathies in the years 1844-5—banded you together in the National Association, enabled you to divide authority with the thitherto omnipotent colleges, and even to overawe a Minister of State? What enabled you to defeat their united machinations? What established you in the estimation and respect of the Government? What was it that

commanded the general consent of all classes of the profession, and taught you to reverence even your own efforts? What was it but the one great and honourable principle—the peculiar master-principle of our day—the principle of education! It may be boldly affirmed that no other single principle is at this time so influential over statesmen, so pregnant with great results to society, or is, in itself, so honourable and ennobling.

Any body of men that seeks reformation upon this principle will always command the attention of a Government, because the claim it enforces is irresistible. It is based in truth, it is associated with truth, and its end is truth. Petty men may seek petty interests, divorced from the general good. They do not comprehend that their interests are inseparably bound up in the general welfare, they do not see that by the elevation of the mass they must be also elevated; but they grasp at apparent benefit with an avidity that blinds their reason and stultifies their judgments. Such men gather fruits that grow over a quagmire; while they pluck them they are submerged in the morass beneath.

I am willing to believe that this so-called Medical Registration Bill is applauded by some men in all sincerity, but I am also sensible that there are many who promote it, and are busy in misleading public opinion in reference to it, who are the mere hirelings of faction and the indecent candidates for notoriety and place. Nevertheless, there are doubtless some who, either from a cursory examination of the measure, or under the influence of sinister advice, or from merely narrow personal views, deem this bill a desirable scheme for settling the differences and healing the breaches that the contentions and asperities of party politics have caused in our profession. If any man thinks that this bill can possibly effect this end, he labours under lamentable delusion; and if any man thinks that because his low objects are temporarily served that the whole profession will hence receive a great boon, the sooner he is stripped of such a hallucination the better for the integrity of his faculties.

What can such a Registration Bill as this do for the profession? The answer was given in the last week's leader of this journal, wherein Thomas Wakley, the author of this measure, was condemned out of his own mouth. He has long declared that "it is objectionable in principle, and must operate painfully and injuriously in practice." Could you desire higher authority? Or have you so mean an opinion of the truthfulness of the man you support, that even now you suspect him of falsehood, and desire my word to vouch for his integrity? If you believe that he has spoken the truth, is it not mere lunacy to grant him support? If you believe him to have been guilty of a deliberate untruth, your confidence is, surely, very inconsiderately bestowed. You cannot complain if you become his victims. Either way you can gain but little credit for sense or honesty. Your name, attached to any resolution in his cause, is the brand of madness or of folly. I rejoice that, notwithstanding all his stratagems, his activity, and his deceitfulness, so few men have been seduced, and have permitted their political honesty to be debauched by his faithless protestations. I had always a high opinion of the members of our common profession: none have had more ample opportunities of estimating their sagacity, their sincerity,

and their zeal in a good cause; and I am pleased to find that the cause of truth and honour has recently suffered so slight a defection of its followers.

The individual, gentleman, who has proposed this measure has advised, with his usual audacity, that the parties who have already petitioned for the passing of his bill shall petition *again*. The ink of the first petition is scarcely dry when the same hand is required to indite a *second*. The honourable member is prepared to practise a gross imposition upon the House of Commons, and he has so contemptible an opinion of your sense of right, that he believes that you will consent to become the shameless tools to advance his sinister purposes! No honest man can acknowledge his fellowship with such profligacy without a blush. If Mr. Wakley is prepared to ring the changes upon a *few* stock petitions, and multiply his one low marauder into seven men in buckram, are you prepared to disgrace your profession by being parties to so dirty a deception? The next proposition we shall have from him will doubtless be—that each petitioner be requested to attach the name of a friend to his memorial. There can certainly be no harm in this—except that it is *forgery*. This is a warning by anticipation: I trust that it will not be wanted.

A cry has been impudently raised against the Council of the National Institute, to the effect that they are opposed to the admission of gentlemen now in actual practice, and possessed of only one qualification, to equal rights and privileges with gentlemen holding a double qualification. Nothing could ever be more audaciously untrue. This right has been long acknowledged, and has been often affirmed by the Institute, as well as by the Association from which it sprung: it is the leading principle in the constitution of both bodies; they are pledged to it, have stood fast by it, and are resolved to maintain it. Let us hear no more of such misrepresentation.

The resolution of the Council of the National Institute which condemned the bill, objected to it in general terms, because "it would permit persons possessing only a single qualification to practise the three branches of the profession." The Council, admitting the principle to which they are already pledged, that persons being now in practice upon a single qualification shall be legalized, objected upon sound and wise grounds that future practitioners, being only partially qualified, shall receive the same indulgence. An act of Parliament has a permanent influence—it is chiefly intended to regulate future affairs, and to regard the future state of the profession; and the interests of a great and learned profession in the future are immeasurably more important than the private interests of a section or a party, in the present—however expedient it may be to consider these lesser interests in a general measure. The Council, therefore, reviewed the bill as legislators; and feeling the onerousness of their responsibilities, not only to the present generation but also to the future, they condemned the bill as tending to lower the standard of qualification, to injure the interests of the profession generally, and to destroy the general practitioner. This is, at any rate, the view I take of their conduct; and I think their proceedings perfectly justifiable and correct.

There is no guarantee in the bill that even the single qualification which the bill requires for practice shall denote a high standard of qualification in that particular branch of study. The colleges, forsooth, are required to submit a

curriculum of study—to whom? To the Secretary of State! This is the sublimity of nonsense. You might as well ask a Chinese mandarin to construct a steam-engine, or to work out a calculation by the binomial theorem, as require the Secretary of State to decide upon the best course of study for the practitioners of medicine. Poor, persecuted man! he cannot even decide upon the best laws for their government—a duty much more within his province than that of acting as high pedagogue to the profession of medicine. Scarcely ever has anything more farcical been imposed on the good sense of the public. Some people can perpetrate drowsy jokes with incomparable gravity. We may depend upon it, that notwithstanding his ignorance, which is proverbially rash, the Secretary of State will not be rash enough to exercise the powers conferable by this bill; and, unless the whole provision become a dead letter, he will appoint a *Medical Board* to assist him in his duties.

But why did not Mr. Wakley provide for this necessary contingency? Simply because he had so vitiated the clauses of Sir James Graham's Bills embodying this object, that even he had not effrontery enough to engraft them in his own; and because, also, it would have been necessary to place on such a board a certain number of general practitioners, which he fore-saw would involve the further necessity of granting a *Charter of Incorporation* to that body. This he is determined to oppose, and he therefore preferred giving, indirectly, an irresponsible authority to a Secretary of State to appoint such a board as he may choose. There can be no doubt that this board of advisers would be composed of physicians and pure surgeons,—of the men who have publicly boasted of their various schemes to degrade the general practitioners, and who have declared that, in the case of surgery, they never intended to fix a higher standard of examination than was necessary "for the ordinary exigencies of surgery."

The standard of education—the only means by which the general practitioner has attained his present respectability and elevation in public opinion—will be diminished; his station will be, consequently, degraded, his influence permanently enfeebled, and his chance of emancipation and independence in his particular corporation forever destroyed.

Are you ready to forego the fruits of a thirty years' struggle in this trickish manner? Are you ready to sacrifice your own class to the ambition and love of notoriety of a restless politician? If you are, support the bill;—if you are not, reject it: there is one hope still for you,—a strong hope and a sure one,—the hope that has already carried you through one hard contest, and will carry you victoriously through another: the hope of a *Representative College* for the general practitioners.

Gentlemen, we must have the *CHARTER*! This is the only means of rendering our class independent, of firmly establishing our professional position, and of securing our respectability, status, and attainments. It is an object within the compass of our means; and will be gained, if we are only firm and unanimous. The Government are prepared to hear, if our demand be sufficiently loud,—to concede, if the force we apply be sufficiently strong and steady. It will be our own fault if we fail to obtain it, as its acquisition will be an honour. I shall add no more on the present occasion, except the ex-

pression of a desire to recal you to this single object, and to induce you to renew your pledges to accomplish its fulfilment.

I have the honour to be, Gentlemen,
Yours very sincerely,
VOX VERITATIS.

MIDWIFERY.—PUERPERAL CONVULSION AND DEATH.

A MIDWIFE'S MIDWIFERY.
Communicated by W. SMITH, M.R.C.S.E.

On Sunday morning, March 7, I was summoned about half-past nine A.M. to visit H. S., residing at Heage (a village two miles distant), who was stated to be in labour. Her father, who waited upon me, said, "that she had been in labour for two days (it was a first labour), and was a good deal swelled, and that her mother was anxious for me to attend her." I inquired if they had got a midwife, and he said he understood there was a woman with her; never mentioned the fact of another surgeon having been applied to, that his daughter was in life. I went over as soon as a horse could be got ready. On arriving at the patient's door, I met with her mother, who had walked on from Belper, and we entered the house together. On my going into the lying-in room, the midwife, Mrs. S., said very snappishly, "We do not want you, I have sent for Mr. E." (meaning another surgeon residing in Belper). I then withdrew from the room, when the patient's mother stepped forward and said, "Mr. Smith, I bespoke you to attend her, and I expect you to go on with it; who has so great a right to interfere as her own mother?" On this, I immediately took charge of the woman, and lost no time in investigating the particulars of the case.

The patient, who was short in stature but perfectly well formed, though under eighteen years of age, was lying upon the bed perfectly insensible, and didn't recognise her own mother; there was stertorous breathing and livid countenance; pupils insensible to the stimulus of light; heid very hot; saliva mixed with blood was flowing from the mouth; pulse strong and labouring, and convulsive action so violent that it required the joint exertions of the midwife and another woman to hold her on the bed. I then examined *per vaginam* to ascertain what progress had been made toward delivery; the head presented, and was low down, but all uterine action appeared to be suspended. Under these circumstances I concluded the case to be one of eclampsia, and lost no time in opening a vein of the right arm; but, not finding the blood to flow freely, I made a still finer incision into a vein of the left arm, from which the blood, very thick and dark-coloured, flowed *pleno rivo*. After abstracting about a pint the pulse became fuller and softer, and the violent convulsive efforts became somewhat abated; the stertor, however, still persisting, I considered myself justified in abstracting four ounces more, after which the arm was properly secured. The patient after this became more composed and opened her eyes, but never spoke; the uterine action did not return, and, notwithstanding the application of large sinapisms to the thigh, which I personally applied, she expired about forty minutes after the bleeding. Deeming it a proper case for a judicial inquiry, I requested one of the neighbours to summon the constable, who I turned with the messenger. From certain inquiries which I made before leaving the house, it inspired that Mrs. S., the midwife, had despatched a messenger to Belper early in the morning (about seven o'clock), to summon Mr. E., another surgeon residing in that place; but we could not ascertain the exact message which he received at Mr. E.'s surgery; neither did that gentleman attend personally, or send any assistance. These circumstances were detailed by me to Mr. H., the constable, who is also registrar of *births, marriages, &c.*, for the district. He stated his intention of riding over to Derby in the afternoon, to acquaint Mr. M., the coroner, with the

particulars; I, therefore, begged he would call upon me on his return, naturally concluding that my evidence would be required.

The inquest was held on the following day (Monday), at eleven o'clock in the forenoon. A Mr. S. attended in place of the regular coroner. The only witnesses examined were Mr. D. E., jun., surgeon; the gentleman who had been summoned but did not attend personally, or send any assistance, and Mrs. S., the midwife. I was present during the investigation, but was not examined; the deputy-coroner, however, politely intimated that I was at liberty to ask the witnesses any questions, and I did accordingly put several questions to the surgeon and the midwife. Now, I must confess that it did seem extraordinary that the deputy-coroner should examine no more witnesses, I would also ask, in the first place, in whom rests the power of summoning the medical witness? Is it at the option of the coroner or the constable? If the latter, did that official (knowing that Mr. E., jun., had been summoned to attend the woman *in extremis*, but did not go or send a substitute, which he had the means of doing) exercise a wise discretion in summoning him (Mr. E.) as a witness? He it understood that there are three other qualified surgeons in Belper besides Mr. E. and myself. Was it possible for Mr. E. or any other surgeon to give an accurate judgment of the case, by merely viewing the dead body (there was no *post-mortem* examination asked for or allowed), and not having any evidence as to the deceased's symptoms, save that of the midwife, a woman totally devoid of education, and somewhat self-willed withal? Would it not have been desirable that the evidence of the neighbours, who were present on the day preceding the unfortunate event, should have been taken touching the strength and frequency of the labour pains, and the progress made towards delivery on that day? Presuming that there had been any neglect on the part of the midwife, in not requiring medical assistance at an earlier stage of the case, was it to be expected that the midwife would criminate herself? Could Mr. E. or any other surgeon (not having seen the patient until twenty hours after death) form a correct judgment as to whether the midwife was blameable or no? Was it not desirable that the messenger sent by the midwife (Mrs. S.) to summon the aid of Mr. E., surgeon, should have been examined touching the time at which he arrived at Mr. E.'s surgery, and the answer which he received from thence? It has been stated to me by a jurymen in respectable circumstances, that the midwife (Mrs. S.) was first summoned to the deceased on the *Thursday night*, and not on the *Friday morning* as she gave evidence on oath to the coroner; and further, that she, on the Saturday, said to the neighbours (who had begged her to send for the deceased's mother or a doctor) "she wanted neither mothers nor doctors." Is not such conduct, if proved in evidence, worthy of a severe censure from the coroner or jury?

GOSSIP OF THE WEEK.

APOTHECARIES' HALL.—Gentlemen admitted members: May 13: William Thomas Gaye, Joseph Delves, James Lewis Holloway, Richard Dechamp Ball, Joseph Williams, William Watts, jun., Benjamin Daniel, Thomas Robinson, and Thomas Bridgewater.

COMPLIMENTARY TO THE MEDICAL PROFESSION.—The Board of Guardians of the Thame Union have furnished their afflicted poor with printed forms, for the medical officers to note in the sick chamber their respective visits after the manner of the excise, as a check in the weekly returns they officially make to the boards!

The trial of the two keepers belonging to the Grove House Asylum, Bow, for the manslaughter of a pauper lunatic, named Rank, took place in the above court on Thursday, the 13th inst. As the facts of the case have been already stated in our columns, it is only necessary to add that the men were sentenced respectively to three and six months' imprisonment.

COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the THEATRE of QUEEN'S COLLEGE, Birmingham.

By SAMUEL WRIGHT, M.D.,

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Cuvierian Natural History Societies of Edinburgh, &c.

Dirt-eating, details of a case of; enormous quantity of Fuller's earth eaten in the space of a year and a half; effects produced by it; treatment; comments upon it; this form of indulgence the result of opportunity, acquired appetites and habits; progressive results of gratifying them; another case of dirt-eating terminating fatally; a third case, less remarkable, and still in continuance; further examples of acquired habits; comments; intentional eating of unwholesome or indigestible food; illustrations; treatment; similar indulgences, the result of depraved appetite from morbid state of stomach; illustrations; treatment; depraved appetite the consequence of uterine disorder, or peculiarity of condition—amenorrhœa, pregnancy; illustrations; treatment.

GENTLEMAN.—In the beginning of November last year, I had a singular case of dirt-eating, in the person of a hospital patient. I will give you its details, with a few comments.

Mary Rodding, aged 20, a light, complexioned, leuco-phlegmatic girl, came under my care, for what seemed to be dyspepsia complicated with obstinate costiveness. At the time of my first seeing her, she had a sallow emaciated look; tongue pale, slightly furred, and trembling when protruded; epigastric tenderness on pressure; pain in the region of the left extremity of the stomach, when this organ was empty, and also shortly after a meal; appetite bad; incessant thirst; frequent eructations, and troublesome intestinal flatulence; bowels confined, often not moved for four or five days together; motions hard, and sometimes nearly round and clay-coloured; urine scanty, with a lithic deposit; there was frequent pain along the course of the transverse colon, but there was no dulness on percussion here, and no evidence, discoverable by the touch, of fecal accumulation. She complained, further, of occasional cramps in the legs, chiefly during the night, which often prevented her sleeping.

On inquiring into the history of her complaint, I learned that she had suffered, in a milder degree than at present, from these troublesome symptoms for the last twelve months: previously to that time she had enjoyed average good health, though she had not menstruated for four years past. Another girl who was with her, and who works alongside her at the business of glass-polishing, informed me that she was certain my patient had gradually begun to fail in her appetite and strength "ever since she took to dirt-eating." This announcement opened a fresh

train of inquiry, and I then discovered that for the previous eighteen months the girl had been in the constant habit of eating large quantities of rotten stone (Fuller's earth), an aluminous material that is used in the polishing of glass. The average amount which she had regularly eaten during this time, as I learned by her own confession, that of her companion, and from other indirect sources, was from twenty to twenty-four ounces weekly. So eager was she for it that she systematically took away a supply on the Saturday afternoon to last her until the following Monday morning. Now, taking the lowest estimate given, viz., twenty ounces weekly, and allowing that, for the first six months, she ate only half the quantity that she consumed during the subsequent twelve (and on careful inquiry I was assured from good authorities that this was much under the mark), even at this rate she had swallowed in a year and a half no less than twelve hundred ounces of aluminous earth! I am satisfied, from the variety of ways in which I obtained my information concerning this girl's practices, from the corroborative testimony of different parties, and from her own confession, which she made the more readily when I intimated how necessary it was to the correct understanding of her case, that I have rated below reality the amount of gratification of her filthy appetite.

It was more than probable that her dyspepsia and constipation were the issue of her unnatural indulgence: the amenorrhœa could not have been consequent upon it, for the menses had been absent for two years and a half prior to her occupation as a glass-polisher.

On the occasion of my first seeing this girl, she was incapable of following her business, and though "pining," as she said, for her favourite ingesta, I advised her to give up the employment that had led to her partaking of it. This I was induced to do, as being the most likely means of preventing a continuance of her baneful habit. Happily I had not much difficulty in persuading her to resign her situation, and felt, additionally, greater satisfaction in endeavouring to remedy the evils under which she was labouring. She was enjoined certain restrictions in diet, was ordered regular exercise when the weather permitted, and the following were her medicines:—

R. Infusi gentiane comp., ℥viij.; ammon. carbonatis, ℥ij.; spiritus ætheris nitrici, 3 iij.; ft. mist. cujus capiat coch. duas amplius in dies.

R. Pil. coloc. comp., ℥ij.; pil. hydrarg.; assa-

fetida, aa. ℥j.; misce in massam, dividendam in pilulas xx. quarum capiat ij. nocte manequ.

On visiting her two days subsequently, I found that she had experienced some relief from her treatment. Her bowels had been copiously emptied of scybulous feces, having little odour, and very much the appearance of rotten-stone. Flatulency was less troublesome, and there was less tenderness in the epigastric region, and in that of the transverse colon. The kidneys were secreting more plentifully, though there was still some lithic deposit; the tongue had a better appearance, and the appetite had slightly improved: in particular, the "craving sensation," which she had previously felt when wanting a natural meal, or her favourite apology for it, was somewhat lessened. She informed me that she still longed, though not so extravagantly as aforetime, for the rotten-stone, but that she had no desire to take any similar material as a substitute. I was told by the inmates, who had carefully watched her, that she had strictly obeyed my orders concerning diet and exercise, and that she had never, since my first visit, sought after any food not suited for her.

At the expiration of three other days I again visited her, and found her still further improved in most particulars. Her appetite had become much more regular and natural, and she had very little epigastric tenderness either before or after a meal: she had less craving for her favourite ingesta, but confessed that, if placed in her way, she did not think she could avoid eating it. Her motions had become natural in colour, but the purgative action being now stronger than necessary, the following pills were ordered:—

R. Pil. coloc. c., ℥ij.; assafœtida, ℥j. Misce et divide in pil. xij.; quarum capiat ij. omni nocte. The mixture was directed to be continued as before.

I paid her three or four subsequent visits, at each of which I found either fresh improvement, or a further establishment of that which had already taken place. I finally transferred her to the care of my able clinical clerk, Mr. Leacroft, under whose judicious management she became fully restored.

The case of this girl is a good illustration of what trifling things may lead to the formation of a bad habit, and what serious things a bad habit may tend to. There can be no doubt whatever that the practice in which this girl indulged was mainly, if not solely, the result of the circum-

stances in which she was placed. Though she was the subject of amenorrhoea for several years, which state often leads to morbid appetites, and to very odd ways of gratifying them, yet this could scarcely be considered as suggestive of her indulgence, for, prior to her occupation as a glass polisher, she had no depraved desires, though she had not menstruated for two years and a half of that time. She assured me that she never in her life had the least desire to put anything not eatable into her stomach, until it occurred to her one day, she knew not why, to bite a piece of rotten-stone. She occupied herself some time in chewing it and turning it about her mouth, and at last, when liquefied, swallowed it. This led to the taking of another piece, and to another, and so on, until the practice became agreeable as a mode of pastime. From this it grew into a pursuit of gratification, and at last the indulgence created a positive appetite. The desire became so strong, and the necessity for its satisfaction so urgent, owing to usage, that even the eating of substantial food did not atone for the absence of the filth longed for. Thus, whenever the inclination grew dominant, it was answered by an immediate partaking of the material sought; and thus, also, was the morbid appetite increased and confirmed. It will hence be seen that, but for the different circumstances in which my patient was afterwards placed, how few would have been the chances of restoring her to health, or of prevailing upon her to avoid a practice which had deranged it.

The remedies which I prescribed for her were just those which I should have given in any other case presenting similar features, whatever might have been the cause of them. The first object, in this instance, was to relieve the immediate distress under which the patient laboured; this was accomplished by the dietetic rules, and the medicines (simple enough) which were given; the second was to prevent a recurrence of the cause—this was happily answered, as I told you, by persuading the girl to employ herself differently to heretofore. I saw her after the complete cessation of her gastro-intestinal ailment, and the commencement of her fresh occupation, and was agreeably informed that she was in good health, and had no desire for a renewal of her old habit.

I learned from this girl, and from others working in the same manufactory with her, that one of their co-operatives had previously, and for a lengthened time, indulged in the same practice of dirt eating. Like my patient, she began quite idly the habit, but persisted in it so determinedly that at last her life was a sacrifice to the sad usage. For some time prior to her death, she lost her appetite, and the only thing her stomach would retain was this aluminous earth. At length obstinate constipation resulted that defied all remedies, and she died, according to report, from inflammation of the bowels.

I know of another instance, at this time, of the same habit, though the quantity of rotten-stone consumed is small compared to that in the two preceding cases, being not more than six or seven ounces weekly. Yet even this one would consider enough to satiate an ordinary stomach after a short trial. This woman, though sickly-looking, says she is in good health, and has no desire to decline her dirty practice. She tells me that she began to chew the rotten-stone more than a year ago, to clean her teeth, and that the habit gradually grew upon her until now, and to forsake it would be the forfeiture of a real pleasure.

So much for custom, and the causes of it! What makes the drunkard, but the first glass? What the inveterate smoker, but the first pipe? What the snuff-taker, but the first pinch? What the most loathsome of indulgers in tobacco, but the first quid? Nay, few are the bad habits or vices that are plunged into at once. Small beginnings generally make good men or wicked ones. A little lie, told in fun, has led to a great lie told upon paper, which the law calls—forgery. Murder in jest, practised upon a harmless fly, has been the foundation of a growing love of

bloodshed, which has had the gallows for its recompense!

This morbid appetite, the result of habit, you often see in different classes of society. I once knew a shoemaker who, from transferring his "wax-ends" to his mouth for convenience, "got so completely into the way of it," as he said, that he was never easy, in the absence of food, without having this said material to chew. You remember the anecdote of a celebrated barrister, who never could plead without having a ball of packthread in his hand, calling it the *thread of his discourse*. No doubt the one, like the other, had begun as an insignificant habit, but at length became a very obstinate one. Some studious men are not capable of prosecuting a train of thought unless they have some particular physical occupation at the same time. Pitt could best reflect when walking to and fro in his room, or in the open air; Sheridan, when staring at a number of lighted candles; Fox, after the immediate exhilaration of friends and a bottle; Gibbon, in the perfect quiet of noon-day; and Byron in that of midnight. Some men cannot study without biting their nails, and will obstinately continue the practice, heedless of pain and disfigurement. A few months ago I was consulted by a celebrated dramatic writer and comedian, during his temporary sojourn in this town, for a soreness at the crown of his head. This part I found to be quite bald, and covered all over with a papular eruption. It immediately occurred to me that there must be some irritating cause. He laughed when I put the query, and confessed that, when in process of thought, he was perpetually plucking the hairs from the spot in question. Of course, I could only advise him to leave off this practice, which he did, and the part became sound again. Some years ago I was acquainted with a man who, though professedly a smoker, yet regularly ate his pipe. Whilst inhaling the tobacco-fumes, he would continue to nibble one bit after another off his pipe, until at last it became too short for service. A relative of mine in this town is in the habit of demolishing the handles of his whips in the same way. These, as I have said, are habits.

Cases are not unfrequently met with in which indigestible or unwholesome materials are conveyed into the stomach with some particular design. It is said of the Athenian youths that they were in the habit of eating cumin-seeds, to give a paleness to their faces, and convey an idea of their studious habits. With the vain intention of preserving his pallor and preventing obesity, Lord Byron was accustomed to use a variety of eccentric means, such as taking a hot bath and a cigar at the time; eating, for days together, nothing but ship-biscuit, and drinking plentifully of soda-water, seltzer-water, gin-and-water, or claret. You sometimes meet with instances of young girls—ay, and old ones too, when they happen to preserve the vanity of early life—eating and drinking all sorts of odd things to clear their complexions, or give them a delicate whiteness. One will gorge great quantities of chalk, another magnesia, and a third starch, to make their faces pale; some will drink vinegar, some brine, and others even their own renal secretion, to answer the purpose of this silly conceit. When a feeling of personal consequence is uppermost, there is no end to the lengths that youngsters will go in the cause of their favourite gratification.

When cases of this kind come before you, your first object should be to persuade your patient to leave off the mischievous indulgence. You will rarely accomplish this by ridicule, or by using harsh measures: either will be likely to confirm the invalid in the bad practice, or to induce a personal dislike to yourself. One of these will be quite sufficient to set aside all chances of your curative treatment. Rather reason with patients of this class: show them, in the first place, the empty, worthless phantom they are pursuing; and next show them the value of an opposite course of procedure. By rational means, judiciously used, you will be able to do far more

in these cases than by harsh or intemperate measures. The one may, and most likely will, reclaim the foolish adventurer; the other will only make him more stupid and determined in his folly. Should remedial measures be required, they will, of course, receive their suggestion from the particular features of each case.

Again, you will find the bad habits I speak of, the issue of a disordered state of the digestive organs. It is seldom, indeed, that you meet with a confirmed dyspeptic who is not perpetually desiring some solid or fluid that is not fitted for him. The generality of your practice will show you that most of those who suffer from disturbance of the alimentary organs are craving for one or other of the particular eatables which your judgment has interdicted. Let the exceptions be very few to a deviation from your original dictate! Not only, however, will unwholesome materials be sought in these cases, but even unnatural ones will be pursued and swallowed with avidity. There is nothing too strange or too dirty for some dyspeptics to encounter. Common earth, dung, cinders, decomposing animal and vegetable matters, and various such things, are amongst the catalogue of edibility which the gastric depravity delights to revel. There is no end to cases of this kind: in a greater or less degree you will find them perpetually showing themselves in your practice.

Your chief business in these instances is to reason with your patient on the absurdity and evil of his indulgence, and next to endeavour to correct the cause of it. To persuade him by moral means of the vice of his habit is a cardinal point: for if he persist in its continuance all your remedies will be useless. The dirt-eaters of the East and West Indies defy all curative measures so long as they persevere in their filthy practices. These stupid creatures, being only partially approachable by rational agencies, can seldom be induced to leave off dirt-eating, when once having begun it; and thus the generality of them are discarded as worthless, after having acquired their destructive habit. Sometimes your patient will make grave promises of abstinence, but not keep his word. When this is the case, you must try one stratagem against another, and, according as your charge attempts to deceive you, find some means or other of detecting him. It is rarely that you can trust to promises in these cases: your patients are bountiful in their intentions, but very barren in the executing of them. Be always upon your guard when subjects of this class come under your care.

The remedial measures to be pursued under the circumstances I speak of are simply those which any particular case of dyspepsia would call for. Look into all the leading features, and your inference therefrom will be your best guide. One will bear one kind of tonic and aperient, and another a different one, and so on. A notion has prevailed, that the material eaten might be taken as a guide to the medicament needed: so that the one who drank vinegar, or ate green gooseberries, should be treated on the acid plan; and the other, who devoured chalk or magnesia, should be treated on the alkali plan. There is no truth in these things. Never let patients' oddities dictate to your judgment: act from your own unbiassed reasoning, and you will generally be on the safe side.

Other cases you meet with in which a morbid appetite is consequent upon uterine causes. In the condition of pregnancy, women sometimes take very queer fancies into their heads, and suggest to you that, if these are not gratified, there is no saying what the condition of the offspring may be. The craving I speak of is technically called "longing"; and by those who are wise in the wisdom of these things, the non-indulgence of this said "longing" is regarded as a sad sin against hereditary rights. Deformities, distortions, mother-marks, and such like, have usually a little history, in one silly mouth or another, reflecting upon ungratified desires. If the various odd whims of people in these conditions were unceremoniously to be

granted, there is no saying what lengths their sympathies and antipathies might reach. I am not disposed to say that any harmless inclination, even though eccentric, should not be indulged, it being provided that the indulgence is fraught with no difficulty; but my experience has taught me that the less conceits and fancies are encouraged in these cases, the better. Once give them latitude and sympathy, and there is no saying where they may end; and depend upon it, they will never want aiders and abettors amongst the kind friends and nurses that constitute the chief company of a sick-room.

The morbid appetite of pregnant women you must control by rational means, as best you can, and trust to a change of circumstances to effect a cure.

In cases of amenorrhœa, you meet with a great diversity of depraved appetite. All kinds of odd things girls will eat, when the stomach sympathizes with a disordered uterus. Coal, coke, sand, dirt, slate-pencil, chalk, paper, book-covers, and other such, are amongst the fantastic crudities in which they indulge. The quantities of these which are consumed are sometimes enormous. Great stomach or intestinal disturbance has often been the issue of the unchecked habit.

Here, again, moral control, in the first place, of paramount consequence; and secondly, should come medical measures. The latter, of course, should consist with the particular indications to be fulfilled. Whether a vegetable tonic, with an alkali or with an acid, or a chalybeate tonic, be necessary, will be determined by the specific features of each case. Appearances you will also give according to the need of them. Horse and other exercise, and change of air, are general propositions which you must apply discretionally.

A COURSE

LECTURES ON SURGERY,

BY

SAMUEL COOPER, Esq., F.R.S.,

Professor of Surgery in University College, London;
Consulting Surgeon to London University Hospital, &c.

LECTURE VII.

The treatment of inflammation, gentlemen, is the next part of our subject to which we must devote our attention. Resolution, as the most desirable of the terminations of inflammation, must be the object always to be kept in view in the treatment of this disease. The hypothesis of Drs. Wilson and Hollis, that the proximate cause of inflammation is debility of the capillaries, and that resolution is effected by the removal of this state by the increased action of the larger vessels, affords by no means a satisfactory explanation of the phenomena. I should imagine, on the contrary, that such increased action of the large vessels would produce a diametrically opposite effect, by propelling a larger quantity of blood into them, and gorging them to the utmost. Our aim, too, in the treatment of inflammation would lead us to employ those measures that we know are capable of producing increased action of the heart; whereas all experience shows that an opposite plan of treatment is the proper one. It being admitted that inflammation is kept up by an excessive flow of blood to the part, the main indication for its removal must be to diminish the determination of blood; and this cannot be effected by any consideration of the exact state of the capillary vessels, or of the motion of the blood in the inflamed part. Indeed, were we to be influenced by such a consideration of the condition of the vessels, the most rational deduction would be to diminish the flow of blood to them, and give time for a return to their natural state. Experience, however, is the best arbiter in this matter; and if we are unable to ascertain the proximate

cause of inflammation in a satisfactory manner, or to reconcile the theories of it with general observation, it is better to dismiss such uncertain hypotheses from our practice, and trust to the results of experience.

The first object of inquiry in any case of inflammation must be the exciting cause, which it is our first indication to remove: for unless this be done we cannot expect to effect a speedy or permanent cure. When, for example, inflammation is produced and kept up by the presence of extraneous substances in any part of the body—when a fragment of glass or a thorn is lodged in the finger—the first indication, and one which would suggest itself to ordinary persons, is to remove the offending substance. When inflammation of the eye arises from exposure to cold, such exposure must be avoided. The removal of the exciting cause will not in all cases stop, or even retard, the progress of inflammation. All living parts are capable of reaction after injury, as shown in the inflammation itself, which is in some cases a salutary process whereby the restoration of the injured parts is effected. Thus we see that, after severe injury of a limb by a bullet wound, or by compound fractures, sprains, or falls, which produce a solution of continuity of the part, certain processes are required to restore it to the natural condition, or to repair the injury as far as practicable. In such cases inflammation is absolutely essential to the completion of these processes, and we must therefore adjudge it to be a salutary operation. You are now in a position to determine the importance of the study of inflammation to the surgeon, since it is more or less connected with almost all diseases, either as a cause, a complication, a consequence, or even as a means of cure; and, however difficult it may be to investigate its intimate nature, the rules of practice, founded on extensive experience, will always remain the same, namely, to lessen the flow of blood to the inflamed part, by bleeding and other antiphlogistic measures calculated to diminish the force of the general circulation.

We have now arrived at two of the most important indications in the treatment of inflammation—the removal of the exciting cause, and the diminution of the flow of blood to the inflamed part. Although we have seen inflammation is, to a certain extent and under particular circumstances, a salutary process, yet it usually happens that from its extent, violence, or situation, it cannot be viewed in this light; but, becoming a dangerous or even fatal disease, demands all our attention to diminish or subdue it. We know that serious results are produced by inflammation, when violent or of great extent, or, again, when situated in important parts, unless quickly subdued by active treatment. The functions of important organs are thus impaired or destroyed, abscesses of considerable size are produced, and the patient often succumbs, under the constitutional disturbance, or local mischief. Even when fatal results do not follow, evils are frequently produced by the situation, violence, and extent of the inflammation, which cannot afterwards be repaired. From what I have already stated, you are aware that it renders transparent textures opaque; that it thickens, hardens, and enlarges the parts attacked by it; that effusions of coagulable lymph are frequent results, which sometimes become vascular and organized, producing permanent adhesions of parts which ought to be capable of free movement. Ulceration and mortification are among its consequences. The structure and functions of organs are either destroyed, or so impaired by such changes that they go on in an irregular and uncertain manner. These changes are well illustrated by inflammations of the eye, in which, if not prevented by timely attention, opacities are produced; the pupil obliterated by coagulable lymph; the iris thickened, or rendered immovable by adhesions; the cornea destroyed by sloughing, so as to permit an evacuation of the whole contents of the eyeball, and collapse and final destruction of the eye itself. In some cases where the iris is

inflamed, adhesions are produced between it and the cornea, or the capsule of the crystalline lens, which prevent the natural dilatation and contraction of the pupila. In fact, the eye furnishes you with a good example of the effects of inflammation: transparent parts are rendered opaque; parts which, in their natural state, are movable become fixed by adhesions; thickenings of the textures; the colourless conjunctiva becoming of a vivid red, the retina paralyzed, and the whole functions of the organ irrecoverably destroyed.

It is not only the destruction of the functions of parts which, however valuable, are not absolutely essential to life, that we have to dread as the result of inflammation, but the injury of those without which life cannot be sustained. In inflammations of the vital organs, activity of treatment is still more necessary, because, if neglected, such injury is sustained as results in death, or the misery of the patient during every subsequent stage of his existence. When the brain, the lungs, the pleura, or the peritoneum are inflamed, you will allow your patient to perish if you do not at once adopt sufficiently powerful antiphlogistic measures.

It, therefore, becomes the imperative duty of the surgeon to adopt the most prompt and efficient measures to subdue inflammation whenever it is of a serious nature. The two principal indications in commencing the treatment of inflammation are, as I have already told you, to remove the exciting cause, and to lessen the determination of blood to the part. The exciting cause is not present in many causes of inflammation; its action, which was only momentary, having altogether ceased. Thus, in the inflammation following mechanical injury, the exciting cause continues no longer than the time required for the infliction of the wound; but a reaction follows which produces the inflammation. In other instances the exciting cause continues, as when sand or other extraneous substances are lodged under the eyelids; and in all such cases it is necessary to remove them as soon as possible: for, until this be done, we cannot expect to effect a cure.

The second indication is to diminish the flow of blood to the inflamed part, and so to remove the perverted action by which the disease is kept up. This indication may be fulfilled either by measures which act directly on the affected part, or by others which act in an indirect manner. Other means of treatment also exist which operate on a different principle, and are founded on a knowledge of the sympathy of different organs. (Counter-irritation) is an example of this kind of treatment which is often of immense utility in the removal of inflammation, when used with proper precaution. Those measures which act directly on the part are called local, or topical; while those which act indirectly on the system at large are called general, or constitutional. The general or constitutional remedies are bleeding by venesection, cupping, and arteriotomy; purgatives; salines; tartar emetic in diaphoretic, nauseating, or even sometimes in emetic doses; perfect mental and bodily quietude, and the careful removal of all stimulants. The patient is, therefore, to be kept quiet, carefully removing all sources of mental irritation or anxiety, which might agitate him and excite the circulation. The local measures are bleeding by leeches or cupping; the application of cold lotions, poultices, or fomentations; and blisters, after depletion has been sufficiently practised. Blisters act in another way, which I shall take a future opportunity of explaining.

Bleeding is the first remedy that should be employed in all acute inflammations of any extent or violence, and such a quantity of blood should be removed as to produce an effect on the whole system. The experience of many generations has demonstrated that this is the most powerful and best antiphlogistic plan on which to rely; and the preservation of life often depends not only on the speedy and free use of blood-letting, but also on its repetition as frequently as the circumstances of the case may

require. In inflammations of all the important organs, of the brain, lungs, pleura, liver, or bowels, the patient must be freely and promptly bled, or life will be lost in a few hours; and, indeed, the omission of blood-letting would give only the poor chance of an accidental recovery. If there were no blood-vessels in parts, or no blood in the vessels, inflammation could not occur; and, if we add to these that the continuance of inflammation is dependent on fresh supplies of blood to the affected part, we shall see good reason for diminishing the mass of the blood in the circulation. By blood-letting the action of the heart and arteries is moderated, the quantity of blood flowing to the inflamed part is proportionally diminished; and in the same proportion the impetus of the blood flowing to the seat of the disorder is checked. There is no case which is more convincing of the great efficacy of blood-letting than inflammation of the tunica conjunctiva of the eye. If we have recourse to bleeding in severe inflammation of this membrane, we observe, that in exact proportion to the removal of blood, the redness decreases, the scarlet colour is reduced to pink, the vessels appear to shrink, and the redness often disappears before the blood ceases to flow from the vein. Here you have a positive demonstration of the power of blood-letting over severe inflammation. In wounds of the head, chest, and abdomen the chief danger to be apprehended is the occurrence of inflammation, and if the patient be not bled to a sufficient extent, after the first signs of inflammation appear, he will soon succumb to the disease. In these cases the surgeon must make up his mind to bleed at once, freely and repeatedly; he must not be deterred by the apparent weakness or smallness of the pulse, for this is commonly a sign of high inflammatory action; nor must he content himself with abstracting small quantities of blood, which will exercise no influence in checking the progress of the disease. Cases have occurred in which so much as three hundred ounces of blood have been removed, and I have myself seen similar quantities of blood abstracted in a short time.

Bleeding is not always necessary in moderate inflammations of parts not absolutely essential to life, although it is necessary in the treatment of all inflammations of important parts. You must also take into consideration, when determining on the propriety and amount of blood-letting, the age, strength, and constitution of the patient. You would not think of bleeding an aged or infirm person to the same extent as a young, robust, and vigorous individual; yet, notwithstanding this, if it be necessary to check inflammation of an important organ, we must rely on bleeding, whether the patient be young, old, strong, or weak, although these conditions would modify very considerably the amount of depletion. You must remember that a small quantity taken from a debilitated or aged person may be equivalent to a large quantity abstracted from a young or strong subject. The utility of removing blood in inflammation is so well established that we do not confine ourselves to general bleeding, but aid its effects by the application of leeches or cupping as near to the part affected as possible.

There are a few persons who, being neither old nor debilitated, are unable to bear the removal of blood to any considerable extent. These persons are characterized by excessive nervous irritability. Andral states that persons who have already lost a considerable quantity of blood during the course of a previous inflammation, or who have been kept on low diet during a tedious convalescence, and are suffering from chronic inflammation as a sequence of the acute form, are apt to have the nervous system violently disturbed by the removal of the smallest quantity of blood. Under such circumstances delirium, coma, and peculiar spasmodic affections may be induced by incautious abstraction of blood; and he mentions a case where the application of a single leech sufficed to bring on symptoms of tetanus. In all cases, gentlemen, it is necessary to study the constitution of your patient, and to

adapt the depletion to his individual circumstances. It is only at the commencement of inflammation that bleeding can be useful to this class of persons, and, if bleeding be not then employed, it must be altogether abandoned.

I have already told you of the assistance to be derived from inspection of the condition of the blood, and from the buffy or cupped appearance presented by the surface of the coagulum. These appearances, joined with other circumstances, such as the state of the pulse, the nature and degree of the fever, and the kind of pain, will usually enable you to judge of the existence, extent, violence, and seat of the inflammation, and to form a correct opinion of the necessity of further blood-letting. In very severe cases it is sometimes useful to bleed to faintness; or, as we say, *ad deliquium*; because, during the state of fainting, all the operations of the system are suspended for a time, and among them, the action of inflammation. In order to induce this state with the greatest promptitude, certain circumstances must be observed. It is necessary to make a large opening in the vein so as to permit a very rapid flow of blood: for the fainting depends in great measure on the quickness or suddenness of the abstraction. It is also proper to place the patient in the erect or, at all events, the sitting position, if not too ill to sit up, and if so he should be supported by the attendants. If placed in this position, the removal of a much smaller quantity of blood produces fainting. In severe cases topical bleeding is used as an auxiliary to general blood-letting; but we must not omit the latter, because topical bleeding alone will not suffice for the subdual of the inflammation. In cases where the symptoms are not sufficiently severe to need general blood-letting, we may content ourselves with topical bleeding; or when, from some accidental circumstance, the patient cannot bear bleeding from the arm. Local bleeding by leeches and cupping is often of great service in cases of inflammation of a chronic rather than acute form. The effect of topical bleeding, where no plethora exists, is greater than might be anticipated from the quantity of blood abstracted. This is accounted for by the proximity of the bleeding to the affected part, by which its vessels are unloaded. We can, however, produce an effect on the system by large local bleedings, either by cupping or leeches. When this is the case, the bleeding may be considered as general. Thus, when several dozens of leeches are applied at once, they remove a considerable quantity of blood, and produce a corresponding effect on the whole system. I have often seen as many as fifty or sixty leeches applied at once; and this is done to a large extent by the French practitioners, who place less dependence on internal remedies than we are accustomed to do in England.

The symptomatic fever which accompanies severe inflammation usually produces more or less constipation. The removal of this constipated state of the bowels is, therefore, another indication in the treatment of inflammatory diseases. We generally prefer mild saline purgatives for this purpose, such as the sulphates of magnesia or soda, or the tartrate of potash and soda. In particular cases more active purgatives are required, and calomel with colocynth, or with James's powder, is preferred. Clysters are sometimes required to aid the operation of these medicines. Mild purgatives have the effect of diminishing the strength and frequency of the pulse, and thereby lessening the power of the circulation. They are useful, also, in producing an increased secretion from the mucous membrane of the intestinal canal. They produce a large amount of secretion from this membrane and when you take into consideration the enormous extent of the mucous membrane, and the quantity of fluid abstracted from the blood vessels, you must perceive the manner in which purgatives produce such beneficial effects.

Mercury is a remedy which exerts a most powerful influence on the progress of inflammation, and more especially in retarding or pro-

venting the effusion of coagulable lymph. This effect of mercury was, I believe, first observed in Germany, but has been insisted on more strongly by Mr. Saunders and Dr. Parre, who found that mercury acted very powerfully in preventing the effusion of lymph in inflammation of the iris, and in promoting the absorption of the lymph when effused. Mercury proves useful in the same manner in acute laryngitis or croup, by promoting the absorption of the lymph effused in the larynx and preventing its further effusion. It is chiefly in these and inflammations of serous membranes that mercury is of such great utility; but in many other forms of inflammation its use is objectionable. It is useful also in chronic inflammation, where there has been a great effusion of coagulable lymph producing thickening and induration. In general the use of mercury should be preceded by depletion—by means of bleeding, purging, and other remedies, I shall hereafter have occasion to notice.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILLSHIRE, M.D. (Edin.), M.B.S., Physician to the Royal Infirmary for Children, &c. &c.

(Continued from p. 250.)

At my last lecture, gentlemen, I was speaking to you of the diet proper to be adopted as regards scrofulous children—a diet not exactly curative of disorder, but rather preventive of its more important outbreaks. Now, after proper diet comes the protection of the body from cold and wet. Of course you know that man in some respects vines great tenacity of organic power, since he can, under favourable circumstances, maintain his proper temperature in all climates, in some of which even native animals can alone exist; in the extreme north, or under the line. But even man, when deprived of the necessary covering and is acted on by severe cold, sinks into a state of stupor, and he does this the more readily according as his food is, or has been, of an improper or insufficient kind. In extreme cases, where the vital energy has been by the latter circumstance considerably lowered, and the loss of heat by external cooling is formidable, a condition of sleep ensues, the vital and voluntary motions cease, and syncope or death result to the sufferer. An analogous, though of course more moderate, condition of low vital energy is seen to take place in scrofulous and delicate-constitutioned children, as in the retardation of the circulation in the extremities; chilblains of the fingers, toes, or even nose; the blueness of the nails, cold lobes of the ears, numbed feet and hands, shrivelling of the skin, and the almost agony some suffer on the accession of winter.

The want of proper clothing to protect the body of scrofulous children not only gives rise to that vital depression of the nervous energy, and retardation of the circulation in the smaller vessels, which sooner or later takes on those low grades of scrofulous inflammation I have before spoken to you of, but at the same time induces such a bad state of action of the digestive assimilation—in fact, of the whole nutritive and formative powers—that tuberculous disorder is excited to unfold itself determinately and fatally in such a child.

The addition of moisture to external cold, and deficient or bad food, add yet more to the aggregate excitement of the scrofulous outbreak.

I advise you to make delicate children wear flannel next to their skin when they are old enough, or the skin not too irritable, to bear it, and not on any account to recommend or even tacitly to sanction the "hardening system." Naked legs and open chests are perhaps, pictorially considered, not unworthy of notice, but hygienically, in this climate, must be held to be ruinous to a delicate constitution. If a parent attempts the conversion of his child into a diminutive Highlander, or one of the Spanish boys of Murillo, ask her, before she does so, to endow it with the necessary constitution for such a meta-

morphosis. It is especially necessary that the *thighs* be well covered, and, in older female children of the better class of society, highly necessary to see that the feet be kept warm and dry. This, I know from experience, is often no very easy matter, as the progressive education of such a patient is that chiefly of appearances: the worsted stocking is ugly, looks yellow, it is thick, and requires a larger shoe—objection is therefore made; but it may be found that a flannel sock reaching only to the ankle will be submitted to, the cotton or silk being worn over it. Sometimes, instead of flannel being worn as bedclothes of different kinds, a sort of compromise is effected by the adoption of delicate merino. Most men would shrink from paddling through the sloop and water which a young female does in winter with stockings and shoes altogether no thicker than her elder brother's dancing-boots.

The only part which I admit of being exposed is the head, from birth (draughts of cool air being avoided); I prefer children to have it uncovered indoors both by day and by night, and out of doors *very lightly* enveloped. The hair should be kept closely cut too, and then many of the troublesome scalp affections, &c., will not be so likely to happen. Constantly keeping the head covered you may depend is a very bad thing. I have been in a Mahomedan country, where of course all the better class of men wear turbans continually, and amongst them scalp affections were very common. The lower orders did not, and they were free from them. I have even seen some of the latter—camel-drivers after having journeyed from Tumbuktu to Swerah, with the scalp exposed to broiling sun, the hair being closely cropped, and yet the scalp was quite healthy. I forget where I read it, but I did, that one great cause of the frequency of baldness in Englishmen was the practice of our mercantile gentlemen wearing their hats so constantly in their warehouses, &c. Whilst, then, you take care that ample protection is afforded the delicate constitution from climatal vicissitudes, you will not of course run into the opposite extreme, of making children hothouse plants. This would be overdoing the mark, and lead to results detrimental in the extreme. One of the greatest errors in this country with regard to clothing, is, that persons dress themselves more in relation to a definite time or period of the year, than in a ratio with the temperature, &c. They leave off a part, or certain article, of clothing, not because the temperature has increased or diminished, but because, according to time, it is the beginning of summer or of winter; whereas, as far as the reason is concerned, it may be quite different in one year to what it is in another. But they follow the rule notwithstanding.

After the adoption of properly-regulated clothing, to obviate the cold and damp air of climate like our own, comes exposure to the fresh air, solar light, &c. The necessity of breathing fresh and pure air, in order to promote a healthy condition of nutrition, &c., is at once apparent; and no worse state can a scrofulous child live under than that of a contaminated, deteriorated air. Therefore, whether I refer to the mere ventilation of sitting and sleeping rooms, or the constant exposure of the child to a pure country air, the rule holds good; and you may at once deduce that the removal of a strumous constitution from the atmosphere of a great town to that of the seaside or country is the thing to be desired. A very good illustration of the great preventive and preservative power of pure air from scrofulous disorder is afforded by some late improvements in the Zoological Gardens at the Regent's-park. There, monkeys were dying continuously of scrofulous diseases; the monkey-house was badly ventilated and overheated, but when it was well ventilated and not overheated, they recovered quickly. The results, also, of the new terrace-dens for the carnivora, exposed to the open air, have been affirmed to be wonderfully satisfactory, authorizing the expenditure of nearly £3000. Scarcely, it is said, had the lions,

tigers, leopards, &c., been a month in their new abode, than a change for the better became apparent. Their eyes assumed a vivacity hitherto unknown, their gait and attitude became more free and unconstrained, their coats acquired the sleek and glossy appearance of their natural state, and their appetite became so much improved that it was found necessary for the council to order increased rations to meet the wants of the animals.

I would recommend you never to allow bed-curtains where a draught can be avoided, and to require that not more than two sleep in the same room. The sleeping-room should be large, airy, and with a fireplace, and the latter not closed by a register-store or a chimney-board. Where two sleep in the same room it is, of course, better that there be two small beds than one large one; where possible, it is of great benefit to be able to dress in a room adjoining the sleeping apartment, and not in the close atmosphere of the past eight hours.

I am satisfied of this, that full exposure to solar light is one of the most important hygienic measures. Far too little stress has been laid upon this, perhaps, partly because it requires a knowledge of some collateral branches of medicine to be able to appreciate its importance in its full force. Those of you, however, who are botanists or zoologists will know what I mean. Still, to others who will call to their recollection the peculiar condition of body, of the glandular structures, &c., of those who live in the deep valleys of mountain chains, of those who reside in narrow, dark streets of northern climates, in mines, of those crowded together in dark cellars and sunless rooms, will easily bring before their eyes pictures illustrative of the effects of the negative of that important vital stimulus—light.

In some manufacturing places the working classes live wholly in cellars, or in courts apparently constructed on purpose to show with how little light a man can just vegetate. It is an often-quoted fact, that monstrous births were very frequent amongst the miserable occupants of the dark dungeons under the fortifications of Lille. The experiments of Edwards on the spawn of frogs and tadpoles clearly demonstrate the agency of light on the formative processes of living organisms; as also those of M. Costa, who placed a number of animals in dungeons without light or space for motion, exposed to cold moisture by means of wet sponges hung up in their cages. Those animals which were not fed upon ferruginous bread became tuberculous. Of course, in many of such cases, other circumstances are in operation detrimental to the economy besides the mere negative of solar light, but every physiologist will be able to appreciate how much is to be laid to the influence of the latter alone.

The child born, then, of strumous parents should be exposed to strong light, often to the direct rays of the sun; if a girl, no such things as parasols, garden-bonnets with long flaps hanging down behind, veils or shades of any description, being permitted to come between her and heaven's beams. The bedroom should be well lighted, and the shutters and blinds never closed, so that the earliest dawn may penetrate the apartment. Undoubtedly, during the sleeping hours, the stimulus of light is not proper, but then Nature has removed it by her natural dark mantle. When she withdraws that mantle, no artificial one should be had recourse to. There is a practice, especially amongst the more educated classes and those of 'taste,' to sit during the daytime in what is artistically denominated 'a subdued light'—that is, the sun and light of heaven are excluded from the room by means of green Venetian blinds and such-like contrivances. However pictorial or poetical such arrangement may be, or agreeable the softened and verdant light which thus enter an apartment, it is physically, hygienically, and medically most improper in a climate like our own. No scrofulous person should be thus treated: let here be no poetizing of him at all.

In the greater number of cases, of course, when you put into force exposure to fresh air and

solar light, you will also involve an amount of exercise, more muscular motion—a point important in the extreme. It should be strongly impressed upon the mother of every scrofulous infant that the moment it can use its legs without danger, when left alone, it is to be allowed to move about in the open air as much as possible; and, if the child be properly fed and clothed, very little attention, comparatively within certain limits, need be paid to the state of the weather. In the better class of society it is a very good way to educate a boy so that he becomes something of a botanist, geologist, and entomologist, as, in following these pursuits, exercise and full exposure to fresh air and light are attained in a manner most beneficial to body and to mind. I need, however, scarcely detain you with impressing upon you the enforcement of exercise; but I may just state that violent forms of it, like certain kinds of gymnastic procedures, which give rise to temporary local congestions of important organs during their performance, are not to be permitted.

Now, gentlemen, if in the hygiene of a child derived from scrofulous parents, or of itself distinctly inclining to the diathesis, due regard should be paid to diet, clothing, and fresh air, &c., a great number of other more or less essential points will necessarily follow in their train. They will of themselves spring out of the others, so I need but hint at them. Thus, if due exposure to air and exercise, &c., be followed, it will be difficult that over-exertion of the mental faculties ensue, or that early or too much schooling, with undue exertion of the mind, be fostered. If proper attention is paid to clothing, the due change of body-clothes will follow, and the highly detrimental custom of allowing garments wet with perspiration, after exercise has been taken, to dry upon the body, will, of course, be avoided. If bathing and swimming for such children be adopted simply as muscular exercise, all that I might say about the value of ablution and cleanliness, at any rate in summer, will be implied. The regulations of nurseries, of schoolrooms, of dormitories; the value of residing in the country or suburban districts, to that of living in great towns; the choice of a business to bring up either a boy, or when necessary a girl, to; or mode of life in which the great hygienic elements exist in greatest perfection, will be all immediately deduced by your attending to the general principles I have already laid down.

Besides, however, the foregoing hygienic preservative or preventive means, there are a few to which I shall just allude, and which may be therapeutic, preventive, &c., measures. The one in which most faith is to be placed is the breathing of an atmosphere which has blown over the sea, and living on the sea effects this most effectually.

The latter part of advice, of course, under present circumstances, can apply only to males, who should be sent to sea very early. But if the advice of a late writer could be acted upon, of having vessels fitted up purposely, and kept constantly moving about at sea, the female children of the richer portion of the community might be kept upon the water; and where, perhaps, two or three children have died from tuberculous disorder, such a mode of life would readily be practised with the remainder until stability of constitution was apparently to be hoped for.

The next is a proposal of the practice of which I know nothing, but the theory of it is not bad, and has been supported by the experiments of M. Coster, and has the authority of Dr. Ranking and some others. It is to give children, decidedly of scrofulous diathesis, ferruginous bread to eat. If I recollect rightly—for I cannot exactly turn to the reference at this moment—children have been fed upon iron bread in some parts of Germany, and with, it is said, great success. Of course, such daily use of iron must be carried on by small doses only; and it could only be under particular circumstances and circumstances that it could be persevered in for any length of time. Onions have been recommended as an article of diet, being supposed to

possess a great virtue in counteracting the effects of a scanty and unnutritious food. The French writers, like Riillier, Barthéz, &c., advise the employment of iron water, sulphurous and alkaline baths, as also ioduretted ones. In cases in which there is supposed to be special tendency to affections of the meninges, the hair should be always kept closely cut, very little covering allowed on the head, and the feet kept as dry and warm as possible. Some, however, go so far as employing, as mere preventive means, acetons in the neck and repeated blisters behind the ears; but these, in my opinion, are more to be considered as curative ones, or attempts at such. Sponging the chest, spine, and abdomen with turpentine embrocations, spirituous and other lotions, is, however, practicable in particular cases, and also the very admirable resource of effusion of the body downwards from the umbilicus with water holding salt in solution, gradually lowering the temperature. When debility of the spinal muscles and inferior extremities exists, and there are no particular contraindicating circumstances, it should be dashed quite hard upon the back. The last advice I shall give is the avoidance of wholesale or continuous purgation, the more especially with mercurials: of the detrimental action of the latter agents I shall again speak.

I shall now pass to the consideration of the curative therapea of scrofula. You would find, perhaps, many who would say that it is chiefly by following out a judicious hygienic regimen, rather than by the use of any direct medicinal agents, that we can hope to effect a salutary change in any scrofulous disorder; I believe, however, that the aid of medicines is far more important than such an opinion would be thought to justify. We know, of course, that all the medicines in the world, without attention to such regimen, would be of no avail; but, at the same time, it is true that the subjection of the patient to a course of medicine whilst under such regimen will greatly tend in the majority of cases to accelerate the cure. In fact, there are plenty of instances daily coming before us in which, although the best rules of hygiene were followed out, yet without medicine recovery would not ensue. There are others, again, who run into the opposite extreme, and who persist in disregarding hygienic therapeutics, trusting alone to the agents of the Pharmacopœia. And if one notion is worse than the other, this certainly is the one which is so. So, again, do we find scrofulous diseases treated as if they were entirely of a local nature, instead of being viewed as the external expressions of a great and fundamental constitutional cachexia.

On entering upon the curative therapea of scrofula, you are to hold the same great doctrine in view which I laid down when speaking of its preventive therapeutics, namely, that you have to deal with a disorder where the main element is that of constitutional debility accompanied with a perverted performance of the offices of nutrition and assimilation. The same conditions, then, of a scrofulous patient having plenty of good food, clothing, air, light, exercise, &c. (no special contraindication existing) are to be as continually kept in mind now as before; and you will constantly find that an additional allowance of meat and some porter will work wonders, whether the patient be a puny, blue-eyed, flaxen-haired little girl, with glandular enlargements or chronic eczema, or a dull-eyed, long-eyelashed, pale-faced, cachectic boy, with a deposit of tuberculous matter. Of course you will meet with plenty of cases in which the powers of the body or of the digestive organs will not bear all the hygienic resources in the energy in which we can employ them when treating scrofula preventively. But the question is one only of degree: the same principle holds good in both. You may know that until late times we have always been in the habit of keeping a patient suffering under scrofulous conjunctivitis under a very diminished intensity of light, or of making him always wear a shade over his eyes; but that now we discard the shade and keep him out of doors, when and

where practicable. So do we confine a diseased knee-joint in lateral leather splints, after we have strapped it or otherwise treated it as circumstances demand, and send the patient out with a stick or crutch, to hobble about in the scene and fresh air, instead of keeping him motionless upon a bed or couch, as formerly. You will observe, then, that some hygienic modes of procedure, at first sight apparently improper to be enforced, are, notwithstanding, of high importance. To these points I shall again allude.

Now, if it be necessary to keep so constantly in view, that the essential nature of the malady we have to deal with is the constitutional cachexia I just alluded to, it will follow that those remedial agents which will be found most serviceable are to be met with in the class of tonic remedies, or are those drugs generally admitted from experience to be able to impart strength and vigour to the system, as the constitutional affection makes itself known by peculiar external manifestations, as shown by glandular enlargements, affections of the skin, the deposition of tubercle, &c., in the texture of organs; certain other remedies, besides what are more strictly called tonics, are resorted to in order to overcome such local signs, and these remedies are such as are considered deobstruents, resolvents, or liqueficients. Some of the agents made use of have also a reputation for an alterative action, as it is termed, and which action is exerted upon the constitutional disorder at the same time that a resolvent or deobstruent one is in force in reducing or dispersing indurations, enlargements, or deposits. Hence, some are given to alter the general marked tendency as well as to cure the local affection.

Although you see we are at no loss in bestowing names upon remedies indicative of particular powers they are supposed to exert, yet I must confess that it is easier to use these names as if they meant a great deal, than to show we have a clear and distinct notion how they do, or that they really do, so act. Still this matters little in practice, after all. Iodine, for instance, is said to be all sorts of things, and to act in all sorts of ways—the truth is, it is very difficult to know what to call it; but not at all difficult to say, and to be sure of this, that under its proper employment glandular enlargements become lessened, chronic indurations dissolved, scrofulous ulcers healed, diseases of the joints improved, chronic hydrocephalus and peritonitis materially alleviated; and not only this, but we can affirm that the tendency of the constitution to the further progress and development of the general malady is altered or put a stop to.

DUMAS ON ORGANIC CHEMISTRY. No. XXI.

(Continued from page 251.)

CHEMICAL PHENOMENA OF DIGESTION.

The theories propounded by physiologists, with the view of explaining the phenomena of digestion, have been, at various times, modified according as the progress of chemistry, by enabling us to resolve, experimentally, some of the difficulties attached to this study, may have introduced into science more positive and precise notions. The hypotheses based on the supposition that the aliments were digested by the effect of trituration, coction, maceration, putrefaction, fermentation, &c., were raised upon data altogether inexact, or at least of too vague a nature, and, consequently, they maintain at the present day, a merely historical interest. We may, however, remark the well-characterized tendency of most of these hypotheses, which incline to reduce the phenomena of digestion to actions of a purely chemical character. In this point, at least, they do not wander far from the truth. In fact, if there be anything clear in physiology, it is that the digestive operations are accomplished without the intervention of that vital force, that unknown agent, heretofore so often and so empirically invoked. But modern researches have clearly established that the changes which the aliments undergo in the

digestive tube are due to a series of reactions of a purely chemical character. These reactions are exercised by the different liquids which are being continually poured out into the alimentary canal.

The ideas held by the ancients as to the transformation of the aliments, and the creation of substances fit for assimilation, could not, now-a-days, be maintained; properly speaking, no organic substance is created either in the digestive tube or elsewhere in the economy. Principles which ought to pass into the blood, to be subsequently added to the substance of the animal, pre-exist in the aliments, or undergo in the digestive tube mere modifications for the purpose of rendering them soluble or of more intimately dividing them. Digestion is, then, a mere solution of the aliments.

This definition is not new. Some of the ancient physiologists asserted that the digestion liquefied the aliments—a fact fully demonstrated by experience, but which required for its explanation the most accurate and extended chemical deductions. In fact, this liquefaction of the aliments is not a simple solution, in the most ordinary acceptation of the term, but a solution of a peculiar nature which is effected by a true action of contact, under the influence of an azotized matter analogous to diastase. This azotized principle, or species of ferment, is met with in the saliva, the gastric juice, the pancreatic juice, &c., and, according to its origin, so has it received different names, although, perhaps, it is but one and the same matter throughout. Thus the aliments do not contain in themselves the ferment capable of dissolving them; this is found in the juices with which they necessarily become impregnated in the digestive tube. If such be the case, if digestion is accomplished only by virtue of the chemical action which these liquids exercise over the aliments, we can at once see that it may be effected even, outside the organism. This has been shown by the celebrated experiments of Spallanzani, as also by the numerous and conclusive researches of Beaumont.

Spallanzani procured some gastric juice by causing birds to swallow small pieces of sponge attached to threads. He expressed these after withdrawing them, mixed the juice thus obtained with finely-cut food, and introduced the whole into small glass tubes which he exposed to the heat of the human body, by carrying them under the armpit. After the lapse of fifteen hours, the aliments were transformed into a homogeneous pulp.

These experiments of Spallanzani have appeared to me perfectly accurate. They have been confirmed by MM. Tiedemann and Gmelin, and especially by M. Beaumont, who was enabled to procure gastric juice in abundance by collecting it directly from the stomach of an individual affected with fistula of that organ. By digesting meat, bread, and vegetables in this liquid, and exposing the whole to a water-bath at the temperature of the human body, these aliments were quickly transformed into a semi-liquid gelatinous mass, in which some traces of vegetable matter were still found floating. These experiments, while clearly demonstrating the solvent power of gastric juice, indicate neither the special principle which effects this solution, nor the manner in which it ought chemically to be regarded. MM. Tiedemann and Gmelin were led to view the free acids contained in the gastric juice as the specific agents in this matter. Having digested fibrine, boiled albumen, mucus, and different animal tissues, with very dilute acetic and hydrochloric acids, they remarked that these substances swelled up, became soft, and appeared partly to dissolve. Still their experiments, and those since made with the same view by MM. Beaumont and Müller, have been far from removing all doubts on this subject, but rather authorize the conclusion that the solution of the aliments is effected under the influence of some organic principle.

Such was the state of the question when, in 1834, the experiments of M. Eberle threw a new

lights upon the phenomena of digestion, by showing that the solution of the fibrinous elements is effected by the undoubted concurrence of an organic matter along with an acid. M. Berreswill found that by digesting the mucous membrane of the stomach, previously washed in water weakly acidulated with hydrochloric or acetic acid, and subsequently dried, he obtained a fluid capable of dissolving coagulated albumen or cooked meat. Some comparative experiments which he performed convinced him that these aliments were dissolved neither by the action of the acid alone, nor by the exclusive influence of the animal membrane. More recently, M. Schwann has shown that the active principle of this membrane is soluble in pure water, and MM. Pappenheim and Wasman have found it to retain its remarkable properties after being isolated and precipitated by alcohol.

On the other hand, M. Leuchs has discovered that the saliva possesses the property of dissolving starch, and transforming it into sugar; his experiments have been confirmed by MM. Schwann and Lehmann, and more recently by M. Mialhe.

All these facts permit us to explain in a satisfactory manner the modifications which the aliments undergo in the digestive tube. Whilst mastication reduces them to a state of suitable division, the saliva, when secreted in abundance, permeates the mass and facilitates the formation and gliding of the alimentary bolus. But the function of the saliva is not limited to this purely mechanical action. According to the experiments of MM. Leuchs and Mialhe, we are authorized in admitting that it may aid in the solution of the starch, which, moreover, explains the fact already observed by several physiologists, that in the stomach starch is partially transformed into sugar. However, the action which the saliva exercises upon starch is, according to MM. Bernard and Barreswill, speedily arrested. These observers have, indeed, shown that acidulated saliva no longer possesses the power of dissolving starch. It then behaves after the manner of the gastric juice, which, they state, dissolves only the fibrinous aliments. Now, the alimentary bolus remains for a very short time in contact with pure saliva, whence we may conceive that this fluid can exercise but a limited influence on the starch; as soon as it arrives in the stomach it changes in nature by becoming acid from its admixture with the gastric juice, and can now act only by seconding the solvent power of the gastric secretion itself.

However this may be, we must admit that the saliva exercises, in a chemical point of view, but a secondary influence in the act of digestion: and this is proved by the fact that in the fish the salivary glands are entirely wanting; while birds, some species of which invariably feed on amylaceous grains, secrete this liquid in but a very minute quantity indeed.

The function of the gastric juice becomes much more important. It is in the stomach that the fibrinous aliments lose their consistence, are softened, and finally dissolved; and these changes, as the experiments on artificial digestion have amply proved, are due to the action of the gastric juice alone. Whilst this solution is being effected, we see the aliments become gradually transformed into a greyish pulp which has received the name of chyme, but of which the composition must necessarily vary according to the nature of the ingested matters. It is, however, certain that the chyme contains in solution the albuminous matters which have to be absorbed by the veins of the stomach to be carried directly into the current of the circulation. There is no doubt but that all the matters which are soluble in water become dissolved by the ingested drinks, and are absorbed with them by the veins of the stomach.

Whilst these reactions are taking place the gastric juice invariably presents a very acid reaction. This acidity is a condition necessary to the action of the gastric diastase upon the albuminoid matters. I have observed that, by filtering gastric juice through chalk, it almost

entirely loses its solvent properties, but that these may be restored by acidulating it anew with hydrochloric acid. MM. Bernard and Barreswill have, moreover, found that, by rendering it alkaline we may destroy its natural action and make it capable of dissolving starch.

In its normal state the gastric juice dissolves the fibrinous aliments with great facility without touching the fatty matters: such, at least, is the conclusion drawn from numerous experiments performed by MM. Bouchardat and Sandras. With regard to the starch, it appears that its solution may commence in the stomach; but, according to the same observers, it is transformed neither into sugar nor dextrine, but gives birth to a certain quantity of lactic acid. However, the greater part of the starch escapes the pylorus with the fatty matters and the residue of the stomachic digestion, and it is in the duodenum and the small intestine that the absorption of these matters is accomplished.

The bile, which in its nature and properties greatly resembles soap, is eminently suitable, if not for dissolving the fatty matters, at least for forming an emulsion with them, and thus presenting them to the orifices of the chyliferous ducts in a state of division favourable to their absorption. To deny the active part taken by the bile in the phenomena of digestion would show a perfect misapprehension of the nature of its functions; we should indeed equally wander from the truth, in regarding it as a product of excretion useless to the organism, as in admitting that it is destined to be entirely absorbed in the digestive canal.

Undoubtedly it is possible that a portion of the elements of the bile may re-enter into the current of the circulation. This appears to be proved by the fact that the excrements of serpents and of some kinds of birds are but slightly coloured, and appear to contain but a very minute quantity of bile. On the other hand, the excrements of the carnivorous and herbivorous mammifera are invariably of a yellow or greenish-yellow tint; and this coloration is undoubtedly due to the bile. But it is difficult to determine whether the quantity of bile which is thus rejected with the excrements corresponds to that which has been poured into the digestive tube, inasmuch as it is almost impossible to attain any precise data in reference to the amount of this fluid secreted by an animal. M. Liebig has asserted, from some experiments performed by Schultz, that the ox daily secretes thirty-seven pounds of bile; and on this unsatisfactory ground he draws a conclusion that the elements of the bile are absorbed anew to serve the requirements of respiration. We say that the result obtained by M. Schultz is unsatisfactory: for this physiologist has arrived in but a very indirect manner at a calculation of the quantity of bile necessary for neutralizing the free acid of the chyme. Everybody must see that the basis of this calculation has no solidity: for how are we to estimate the quantity of acid liquor secreted by the stomach which really passes into the intestinal tube, or how take account of that which, being formed in the stomach, is, on the contrary, directly absorbed by the veins of that organ?

From the foregoing facts we can readily understand that doubts may still remain as to the function of the bile in the economy: for, although it may be certain that this liquid serves to form an emulsion with the fatty matters which should be absorbed by the chyliferous vessels, it is not so easy to say what becomes of its elements, when once this first-named function is accomplished. With most animals, a portion of the bile is rejected along with the excrements; but it is far from impossible that another part may be absorbed anew by the organism. The bile is a liquid very rich in carbon, and which contains sulphur as a non-oxidized body; it is in some sort a combustible product very different from the urine in which we meet only with oxidized bodies. This peculiar constitution appears to support the opinion which invests the elements of the reabsorbed bile with an active influence

in the phenomena of respiration. If such be the case, it must be absorbed by the mesenteric veins: for the chyliferous ducts are never found to contain bile; and indeed these latter vessels appear to absorb from the digestive tube merely the fatty matters, and perhaps the products resulting from the solution of starch.

In fact, it is principally in the intestine that the fecula is transformed into dextrine and sugar, and this transformation is accomplished by the action of the pancreatic juice. The pancreas, which in its anatomical conformation so greatly resembles the salivary glands, like these latter secretes an alkaline liquor which, according to the experiments of MM. Bouchardat and Sandras, rapidly transforms starch into dextrine and glucose. We may then affirm that the action of the pancreatic juice is in some sort supplementary to that of the saliva.

The following is the mode in which the solution of the principal substances contained in our aliments is accomplished. In the stomach, the albuminous matters are chiefly digested; in the intestine, the fatty and feculent matters. This digestion is effected under the influence of an azotized principle analogous to the ferments, the properties of which are modified according as it may be dissolved in an acid or in an alkaline liquor. We thus see that the phenomena of digestion are closely allied to those which have been long known under the name of fermentations, or actions of contact.

Such are the most evident consequences which may be deduced from the numberless researches which have been instituted on the subject of digestion, and among which, beyond the classical writings of Spallanzani, Tiedemann, Gmelin, and various other physiologists, we must particularly instance those due to M. Blondlot and to MM. Bouchardat and Sandras.

OBSERVATIONS ON THE ACTION OF MERCURY IN INFLAMMATION, AND ITS EFFECTS ON THE SYSTEM.

By HENRY SMITH, M.R.C.S.

Late House-Surgeon to King's College Hospital.

(Continued from page 215.)

In the last paper I mentioned some of those diseases in which mercury acts beneficially; and it was found that these diseases consisted of inflammatory attacks, either acute or chronic, brought on by various circumstances, causing the formation of certain products which quickly tend to spoil the part attacked. There are certain forms of inflammation, however, in which it would be useless and injurious to give mercury: I mean those which are caused by a poisoned state of the blood, are accompanied by a low state of nutrition, and an unhealthy formation of those products which are essentially the characteristics of inflammation.

I have already mentioned that, in scrofulous inflammation, mercury is likely to do harm, and have quoted the opinion of Sir Benjamin Brodie, which is to that effect; at the same time it must be confessed that some high authorities recommend it in certain forms of this peculiar inflammation, amongst whom we find that justly celebrated physician and acute observer of disease, Dr. Graves. He recommends the adoption of the plan of speedy mercurialization in scrofulous affections of the lungs, and asserts that he has been able to check incipient phthisis in this way; and Dr. Munk has written a paper on the same subject, and gives cases of this disease in which a cure was brought about under this plan. Dr. O. Beirne has also called the attention of the profession to the good effects which mercury has over scrofulous affections of joints; therefore, although we know that the mercurial action on a system depressed by scrofula must be in many cases theoretically and practically bad, and that the practitioner is by no means warranted to give it indiscriminately, certain cases may be

in which, as these authorities certify to, it is so productive of benefit.

Certain formidable inflammatory attacks of the serous membranes are liable to arise during the course of some diseases of the kidney, and are dependent upon some material which is retained in the blood, and is exerting a baneful influence on it. In consequence of the severity and rapidity of these attacks, mercury has been employed as in other cases; but if we consider for a moment of what nature is the inflammation, from what cause it has arisen, and what is the particular state of the system thereby induced, we shall be led to question the propriety of giving mercury at all.

This inflammation, as I have stated, is the consequence of a poisoned state of the blood, and the products formed are abundant mostly of a fluid nature, and of an imperfect and unhealthy character. The condition of the blood itself is much altered in consequence of the disease of the kidney. Its albumen has been draining away in large quantities, and the red globules have been destroyed. As we might expect, then, the symptoms attending such attacks are often of a low form, and the constitutional powers are much depressed. Mercury must necessarily prove deleterious in such a state of the system; the blood is already somewhat in the same condition as that produced by mercury, it has been noticed, also, that salivation is very easily produced and is with difficulty checked, and yet, notwithstanding, little benefit has resulted.

Opinions, however, on this point are on others, differ much, and it is but fair to state the opinions of those who are best calculated to give them. If we look into the writings of the three most celebrated authors on medicine at the present age, we find the following. Dr Watson, whilst speaking of renal dropsy says, "It is yet an unsettled question whether mercury be advisable or even admissible in these cases; the current of medical opinion sets against it, perhaps too strongly. It has been observed that salivation is apt to be produced by a small quantity of this drug, and to be unusually troublesome and severe, without bringing any commensurate advantage. I mentioned to you formerly, Dr Ferri's opinion that mercury has the property of rapidly destroying red blood, and so, it must be considered rather an ally than an antagonist of this maldy. On the other hand, some patients have appeared to recover altogether after passing through a furious salivation." Thus he hesitates to give a decided opinion, either for or against it.

Dr Graves in his "Clinical Medicine," article "Serulima," gives the description of a case of renal disease accompanied with chest affection and effusion into the peritoneal cavity, in which, after using other treatment, he says, "I then ordered mercurial frictions to the abdomen and villi, and gave mercury internally."

Dr Copland, whilst speaking of the treatment of pleurisy as a consequence of renal disease, says, "The best action to effusion requires the prompt use of suitable means, but these means are not the same as are generally found serviceable in the early stage of common pleurisy; bloodletting and mercury must be sparingly, cautiously, or not at all prescribed."

I myself have attended one or two striking cases of inflammation from renal disease in which, from the severity of the symptoms, mercury appeared to be indicated, and it was given, but in these cases the use of this remedy was attended with results which would make me cautious in its employment in such cases.

Certain inflammatory attacks arise during other diseases dependent upon morbid poisons—as erysipelas, phlebitis, and measles. The lungs and pleura are chiefly the seats of inflammation. Mercury, as a general rule, may be dismissed from the list of remedies in such cases. We must recollect upon what the inflammation depends, and act accordingly, by treating the general complaint internally and skilfully. The local inflammation will yield—as an instance, I may

mention that I have seen most intense inflammation of the lungs, caused by the poison of erysipelas, cured chiefly by the exhibition of brandy and other stimuli, and local counter-irritation.

There are also other inflammations dependent upon morbid poisons, in which the use of mercury is not followed by that benefit which we might expect for, although these attacks appear to be of the same nature and attended with the same results as those produced by ordinary causes, it is found that the same treatment is ineffectual, as an instance I may mention the difference between the treatment of two varieties of mitis—syphilitic and rheumatic in both forms of this disease—the same structure is affected, and the same products are effused, yet the one most imperatively demands the use of mercury, whilst the other is cured by colchicum and quinine, and very frequently resists the mercurial treatment.

Thus we see how essentially different the causes of the same disease are, and consequently how different their treatment should be, and it is by finding out these causes, and adapting his practice to the knowledge thereby he has acquired, that the rational practitioner differs from him who, led by a blind empiricism, merely treats a disease by its name, not finding the varieties it may assume when acted upon by peculiar circumstances.

Having thus shortly reviewed some of these diseases in which mercury may or may not be employed, I shall conclude these observations with a few remarks on the mode of administering it, and for treating the immediate illness which some persons sustain its administration.

Undoubtedly the success of any remedy depends much upon its being properly given, and in no one less than this holds so much as in mercury. We have a powerful mineral, possessing most useful qualities, at the same time able to do immense mischief. Before then, with such a compound as we should administer with caution in almost all cases, and take care that we treat not any one of its functions, instead of one of defence and salvation.

The grand object we wish to attain in the administration of mercury is, to get the system affected by it in fact, in other words to get it absorbed into the blood, and thus to change its constituent parts.

The system may be affected rapidly in two ways, namely either by giving a large dose at once, or by employing small doses at frequent intervals. There are some who use the first method, and Dr James Johnson would justify it. But Dr Graves has written in favour of administering large doses of calomel in acute inflammation, and he says that this practice was attended with no danger, and that the curative effects of this mode of giving calomel were most striking.

The objection to this plan is, that we cannot in any case judge beforehand what precise effect mercury will have on any single individual, and thus, in giving a large dose of mercury, we are making a bold stroke in the dark, and are using a weapon which cuts on both edges, and over which we may lose our control. In how severely will ten grains of calomel sometimes salivate, and what distressing effects will it produce! and should there be any peculiar susceptibility of mercury, such a dose might destroy life, or produce lasting ill effects.

There are some cases, however, in which it is necessary to affect the system in a few hours, and, as it can be done in this manner, it would be advisable to put it into practice. In such a case, as in most others of acute inflammation, calomel is the best preparation. One scruple is the dose generally recommended, and, if that fails to produce the desired effect, it should be repeated in grains, still frequently fairly and fully salivate within a few hours of its exhibition.

Put the mode which is generally used, and which appears to be the safest, consists in the administration of small or moderate doses at

short intervals. This plan is perhaps inferior to the other, for this reason, that the object we wish to gain is not so quickly obtained, but, on the other hand, it is superior inasmuch as small doses are not so liable to produce such severe effects as large, and the remedy in that form is more under control. The dose employed varies from gr. j to gr. ij, repeated every two, three, or four hours, according to circumstances. Calomel, as I have before stated, is that generally used in acute cases, from reasons which are obvious.

To produce a decided effect, other remedial means should be used, which will promote the absorption of the mercury, and which will render the system more capable of its influence. Thus to give mercury every three or four hours by itself, without any other treatment, during the height of an acute disease, when the powers of absorption are at a stand-still, is injudicious. If the case will admit of it, blood should be previously taken away, the bowels should be well cleared, and medicine be given which may diminish the action of the heart, and lessen that febrile disturbance which is inimical to a proper action of mercury. In many instances we shall be able easily to affect the mouth by this method, the period will vary according to the disease is more or less severe, for doubtless the nature of the attack possesses influence over this matter, thus how striking to any observer is the difficulty of mercurializing a patient with rheumatic fever! Dr Todd first called my attention to this point, and I have since noticed it particularly. This difficulty is also apparent in some acute attacks, and it must be looked upon as of bad augury, if such should be the case, the medicine must be steadily persevered in, if there is no contraindication. The dose may be increased or rendered more powerful by the admixture of blue pill. Type system properly we shall in many obstinate cases be able to affect the system, and when this takes place, there is but little to be remarked abatement in the symptoms; the heat of skin is less, the action of the heart and lungs less embarrassed, and the action of the heart. The practitioner I say, I have observed this difficulty, but the case he feels that the disease is to a certain extent brought under his dominion, and in many cases he can look forward to a permanent termination. Any one who has been anxiously attending a severe case of inflammation, and has relied chiefly upon the use of mercury must have experienced this feeling, when he has seen the inflammation which takes place in the mouth being allayed.

There are some who say that this improvement is not due to the mercury, but that the abatement of the febrile symptoms is the cause of the system becoming affected, therefore of any benefit to the remedy. The fact however is certain, that on the mouth becoming affected the symptoms in a great number of cases decrease in violence, therefore we must be content with that, if we cannot perfectly understand the explanation. If a person is about to undergo a course of mercury for any chronic disorder, it is essentially important to employ some preparatory treatment, as the successful issue of the case will much depend on this. How often is mercury given to persons labouring under some syphilitic affection, merely as a matter of routine, and as though the mineral was as free of action and as harmless as any other agent, how frequently does it disagree with the constitution, and fail to produce its desired effect, from a neglect of those cautions which should always be given to any one taking mercury!

The preparatory treatment I need not dwell upon, but there is one point I will make a few remarks upon. Sometimes it is found extremely difficult to salivate a patient in the ordinary manner, although the mercury may be carefully given. In such a case the functions of the various organs should be well attended to, the skin should be particularly looked after, by allowing the patient to take a warm bath, and combining a sudorific with his pill, the difficulty will be in many cases got over; at the same time the diet

must be carefully regulated, and the clothing of the body be carefully attended to.

There is no doubt that an increased secretion of the various secreting organs is a part of the great specific action, and that, unless this takes place, the beneficial influence which we expect will not take place. For instance, if, during the employment of mercury, the skin becomes hot and dry, the salivary glands become excited without secreting, and at the same time an over-secretion from the bowels takes place, the remedy is not acting properly, and will be useless for us to look at the gums day by day. We should examine the state of other parts and functions, and not be content with looking at the mouth only. I will quote a passage from the work of a man, who perhaps attends more to the action of mercury than any other, which bears upon this point. Matthiæ, speaking of the exciting causes of what he called the mercurial disease, says, 'Among the exciting causes of this disease we must reckon that kind of constitution which resists the action of mercury; for the secretions, particularly those of the salivary glands, or rather in which mercury acts on the mouth, skin, and kidneys in checking, instead of increasing, the secretion. This kind of habit of all others is the most unfriendly to mercury, and the soonest takes on the specific disease of the mucous, and it cannot too strongly engage our attention, as much of the knowledge of the disease, of its phenomena, and of its treatment depends upon it. Indeed the specific diseased action of mercury is always connected with this check on the secretions; for although the venereal virus is not destroyed merely by evacuations, we know that except the secretions are in some measure excited by mercury, the virus will not be removed, and we find that in all cases mercury is the least liable to run into its morbid action when the secretions are increased, and especially those of the mouth and of the skin.'

(To be continued.)

PRACICAL OBSERVATIONS RELATIVE TO THE MANAGEMENT OF THE INSANE.

By WILLIAM SMITH M.B.C.S.

Formerly M.D. at the Lunatic Asylum, in the County of Lincoln.

"My chief aim is by very simple efforts, to reach the truth, and to let it be my first object to let it be true, and to let it be true."

(Continued from p. 136.)

Manslaughter in a private madhouse, the admission of the public eye, the only safeguard to the lunatic, the only advantage in this respect of public hospitals for the insane, or private madhouses, is the improvement in the treatment of patients in the Royal Hospital of Bethlem, and the progressive diminution of mechanical restraint, as shown by the official reports of that establishment.

The newspapers contain an account of manslaughter at a lunatic asylum. The prisoners were committed to Newgate for trial, but being refused, considering what has lately been published, relative to the improved treatment of the insane, and the humane measures said to be adopted towards those unfortunate individuals, we are scarcely prepared for such an outrageous and disgusting scene as is here presented to the imagination. In our public hospitals such outrages are now, I believe, extremely rare, but in the *lunatic houses*, the *private madhouses*, such occurrences (or something little better), I fear, are still frequent. That in my and very gross abuses do still exist in these *private madhouses*, we need only refer to the infamous state of the Haydock-lodge Asylum (under the kindly auspices and humane control of an excellent poor-law commissioner and poor-law auditor), so thoroughly exposed in the *Times* newspaper for August 27, 1846, and the official report of the commissioners in Lunacy—a combination of individuals chosen on the basis

a *non lucendo* principle. Having given this matter a considerable degree of attention, and been somewhat of an amateur in all matters relating to madhouses, or, as they ought to be, hospitals for the insane, I will give my opinion why the *private madhouses* are so much inferior to the *public hospitals for the insane*. In the former establishments (in too many instances) the patients are looked upon as matters of commerce and trade; the longer they remain, the better for the proprietor, if this proposition be correct, the more they are beaten, the worse they are, and the more fluid and unnutritious their diet, the better for upon these points most materially does the career of an insane person depend. If they are bled and blistered and stoned (see Commissioners' Report of West Auckland Asylum "The medical attendant considered that 'bled, purged, and stoned,' were the principal resources of medicine for relieving maniacal excitement"), and kept upon low diet, no doubt the proprietor will be enabled to retain them for some time. Again, the *lunatics and nurses* (an expensive item in a madhouse) are not allowed very high wages, and *street waifs*, being much more common, will frequently be substituted for extra keepers or nurses. And last, though not least, the public eye is most carefully excluded from these *private madhouses*. Should a medical man who is properly acquainted with insanity request permission to inspect the establishment, he will assuredly meet with a denial, and the plea will be, 'it will be the following: "The friends of the patients have given us strict charge not to allow them to be looked at." Poor deluded mortals! they are like a flock of sheep who have placed their lives at the mercy of the wolf, having first taken the precaution to secure their proper guardian, the dog. In order to prove that public inspection is the greatest safeguard from abuse which the lunatic possesses, I will refer to the deliberately recorded opinions of a physician who has for more than thirty years devoted his talents and energies to the cause of the insane—Dr. Charlesworth, the senior physician of the Lincoln Asylum, in a letter addressed to a General Board of Governors, October 12, 1828.

If the public eye may be deemed necessary to prevent or counteract defective treatment in public hospitals for the insane, how much more is it absolutely required in the case of a private madhouse, where the unhappy lunatic is subjected in too many cases to the fondness of ignorance and suspicious proprietors, and a set of brutal and uneducated keepers and nurses, who give no more practical acquaintance with the treatment of insanity than has the Pope at Rome. But there are many gentlemen of honourable character, and great professional ability, now superintending private establishments for the insane. I will most readily admit. But whilst we have so fresh in our recollection the horrors and atrocities of Haydock-lodge—whilst we are aware, in the official report of the learned commissioners in Lunacy, the number of abuses existing in the private asylums at West Auckland, Wreckington, and Galeshead, Dr. Charlesworth's *genius*—so long as these things continue, I shall incline to the opinion, that public hospitals, such as Northampton, Gloucester, Lincoln, and Multis alius, are preferable for the cure or retention of insane persons, let their condition in life be what it may.

So strong is my opinion on this subject, that, were I manly to inflict any member of my family or connections, my most strenuous exertions should be used to prevent their admission into a private asylum. It may be all very fine to boast of the efficiency of our commissioners in Lunacy (a hybrid race of *brilliant bristlers* and *aged physicians*), but, until that board shall be constituted of very different materials to what now enter into its composition, until it be composed (as undoubtedly it ought to be) of men who have gained a practical acquaintance with insanity in the wards and at the bedside of patients in our large public hospitals for lunatics, until that happy day arrives, I shall beg to retain my pre-

sent opinion, that the *free admission of the public eye* is the only safeguard from abuse which the lunatic possesses.

Having had occasion last week to remove an insane female to the Royal Hospital of Bethlem, I took advantage of the opportunity to inspect that fine national establishment, which I did in company with its physicians, Dr. Monro and Sir A. Morrison, who kindly allowed me every facility of observing the condition of the patients. I have thought it right on several former occasions to expose what I considered objectionable features in the management of Bethlem. My present task is a much more agreeable one—that of almost unqualified approbation. The patients, with one or two trifling exceptions, were remarkably quiet and orderly; the walls of the ward, in fact, every part of the house and office scrupulously clean, and (what is rare in many asylums) devoid of bad smells. There were not more than three or four patients under seclusion. One male patient was restrained, his arms being secured in a kind of slop, so that he could not make use of his fingers. I must confess now, as heretofore, my unquenchable dislike to any system of mechanical restraint. If insanity be a disease wherein the patient labours under accumulated nervous excitability, can it be reasonable, or according with physiological principles, to repress the free movement of the limbs? There is a great analogy between children and insane persons: confine a child in the house, on a wet day for instance, what is the result? Why the child becomes fidgety, restless, and troublesome, and, ten to one, annoys every person about it, but let the shower pass over, and the sun break out fresh, the child eagerly petitions to go out and play, so soon as the limbs can have their free exercise, the accumulated irritability, like *Hubb's* valour, comes out at the fingers' ends. Now, a knowledge of this peculiarity in the insane, and acting in conformity with it, will just make the difference between a good and bad attendant. An experienced attendant, like a wise physician, will give nature fair play, and limit only where his services are absolutely required. The medical superintendent of an hospital for the insane stands in a similar position to his attendants to that occupied by the colonel of a regiment: he it is who must manage them and put them through their different evolutions, if he wish to do any good with them, he must study their various dispositions and capabilities as a schoolmaster scrutinizes those of his pupils, a correct knowledge of these particulars, and many others equally important, is the only sure basis upon which he can ground his management. Now, if my views be correct, and I think really practical men will be in me out in them, what must that man have to encounter who is called upon to preside over a leviathan establishment like Hanwell? That one man (even gifted with the conjoint wisdom of Nestor and Ulysses, and possessed of the united powers of Ajax and Achilles) can exercise the necessary control over such an establishment of attendants (putting aside the patients), is morally and physically impossible. That the visiting magistracies of Hanwell, assisted by that doughty champion, the *looker-on*, have done much towards benefiting the insane, I will most readily admit, but that the present system of filling the house with *incurable patients*, frequently, I fear, almost to the exclusion of *recoverable* and *curable* ones, can be advantageous, no one practically acquainted with the subject will admit. The commissioners in Lunacy, on these points, have certainly done nothing more than their duty. As it is quite evident that further accommodation will shortly be demanded for the insane in the county of Middlesex, I would respectfully suggest that a new hospital or two (each capable of containing not more than 200 patients) be erected for the recent and curable cases, and that the present establishment be used for such as have become chronic and incurable. But to return to the Royal Hospital of Bethlem. Many improvements have recently been effected, amongst which I would mention

the admission of pupils. On one point, however, I am not agreed with the governors of Bethlem: why restrict the pupils to two, and why confine the boon to the two royal hospitals of St. Bartholomew and St. Thomas? Are we to understand that there is only a royal road to learning? What have the pupils of St. Bartholomew or St. Thomas done to signalize themselves above the students of other schools? Have not most of the honours distributed at the London University been carried off by students of University College, King's College, and Guy's Hospital? Why not admit a pupil from every metropolitan hospital? The number would be no disadvantage. Let the two physicians, Dr. Monro and Sir A. Morrison, give a regular course of clinical lectures on insanity; they have ample materials, and either of them is, I imagine, fully competent to the task. The valuable lectures of Dr. Conolly, the talented physician of the Hanwell Pauper Asylum, have given great satisfaction, and will prove beneficial in imparting practical knowledge to country surgeons who have not had an opportunity of studying the disease. As this branch of medical science becomes better understood, there will be fewer accounts of bleeding, blistering, setons, turpentine, and other antiquated remedies, now (very properly) almost exploded from the list of scientific remedies. In place of *strait waistcoats and leg-locks, restraint-chairs, &c.*, we find *workrooms filled with orderly and contented patients, wards formerly echoing back shrieks and execrations are now decorated with fancy garlands, and anon resound to the merry dance. The goddess of discord has taken flight, and what was once a pandemonium may now, comparatively speaking, be likened to the Elysian fields.*

In the matter of restraint the governors of Bethlem made rapid strides. In their General Report for 1841 they observe—

"It is almost unnecessary to say that restraint has diminished just as the means of occupation and amusement have been increased, and that without such means and appliances it would be injudicious to attempt to dispense with mechanical restraint; and in judging of other institutions this ought to be carefully borne in mind, to prevent a hasty and unintentionally unjust conclusion."

Although the Lincoln Asylum has many defects, the most glaring of which is, the difference of opinion prevailing amongst its medical officers, I will venture to assert my belief that this small establishment, containing under 120 patients, has introduced a greater variety of, and more really valuable, improvements in the treatment of the insane than any single establishment in this or any other country.

Belper, South Derbyshire, April 21.

STRANGULATION OF THE INFLAMED SPERMATIC CORD SIMULATING SYMPTOMS OF STRANGULATED HERNIA.

By Dr. MONRO.

Translated for the MEDICAL TIMES by ALBERT MARKWICK, Esq., Surgeon to the Western German Dispensary, and formerly Lecturer to the Venereal Hospital, Paris, &c.

The silence that has been observed on this subject by the authors of the various works on surgery is no doubt to be attributed to the very few examples that have been met with of cases of this kind. Nowhere do we find any detailed description of them, and even in the writings of Sir Astley Cooper we find merely a passing allusion to the fact which leads one to suspect the possibility of such an occurrence. We think, therefore, that it may be useful to awaken the attention of surgeons, in order that this hiatus may be filled up at some future time, when a sufficient number of cases have been collected and published.

In the month of March, 1816, a patient placed at No. 30, Ward St. Jean, Hôtel Dieu, Paris, under the care of M. Blandin, was attacked with hemorrhagic orchitis on the right side; the cord was swollen and painful, and the swelling extended into the inguinal canal. Sud-

denly, this man became seized with very violent pains in the abdomen; there were constipation, hiccough, and nausea; and to any one who had not previously seen the patient, the tumour which existed in the right groin would have appeared, on carelessly examining it, as if formed by a strangulated hernia. Probably in this case some doubt might have existed, notwithstanding the utmost attention was paid in its examination, had not precise information been given respecting it. Besides, it was possible for an error to have been committed, inasmuch as in a similar case MM. Dupuytren and Margolin were deceived by the symptoms. Sent for to a patient who had been suffering for two days past from nausea and vomiting, and who complained of very acute pain in the abdomen, but more particularly in the inguinal region, and perceiving a swelling in this region, and feeling an enlargement in the inguinal canal, they were of opinion that a portion of the epiploon, or else a small loop of intestine, had become strangulated in the canal, and that an operation ought to be immediately performed. Dupuytren made an incision along the course of the canal, opened it, and found nothing but the tumefied cord, and they were greatly astonished to find all the symptoms disappear after the operation, which they believed to have been unnecessary. M. Margolin then put forth the idea, that, without supporting it, all the symptoms above mentioned might probably be due to the compression of the cord. It was he, also, who related this case to M. Blandin, on seeing, a few years afterwards at Beaujon, a patient whom the latter professor had operated on from the same cause, and in whom the symptoms had likewise disappeared on the opening of the inguinal canal.

Such is a summary of the only facts I am acquainted with relative to the question under consideration. I think that in practice similar cases are sometimes to be met with, which pass unnoticed, or unexplained, and this is why I am induced to mention them, in order that they may all be collected, and the question more thoroughly investigated.

As will be seen from the foregoing observations, it may happen that the testicle and the spermatic cord become inflamed and simulate a scrotal hernia (orchecocele), particularly the congenital variety; or that the cord alone becomes swollen and resembles bubonocoele. It may here be stated, that it is in the latter case that an error of diagnosis is most likely to occur, since it has been committed by the justly celebrated surgeons I have already mentioned.

If a man falls on his abdomen and receives a violent blow on the inguinal region which gives rise to very acute pain along the course of the canal, and a very painful irreducible tumour—moreover, if he complains at the same time of violent colic, and there are constipation, hiccough, nausea, and vomiting—where is the surgeon who would not at first attribute the symptoms to a strangulated hernia rather than to an inflammation of the cord, more particularly if they made their appearance after a violent effort. And such an occurrence may take place, for on three different occasions in hospital practice we have met with cases of orchitis and inflammation of the cord which arose from no other cause indeed it has already been referred to by several authors, the majority of whom consider it to have been occasioned by the cord having been violently constricted by the inguinal canal, in consequence of the energetic contraction either of the externa oblique or of the rectus abdominis muscle. M. Velpeau even admits only the action of the latter. He says:—"The disposition of the muscles and aponeuroses of the iliac region appears to me to explain that fact without difficulty. If we carefully follow the fibres of the rectus abdominis muscle, we then see that some of them detach themselves inferiorly from its external border, in assuming a fibrous character, and, passing outwards in the form of a loop beneath the vas deferens, terminate on the internal border of the iliac crest. These fibres form the lower

half of the abdominal opening of the inguinal canal, being thus more elevated by their extremities than by their centre. The rectus muscle cannot contract without their concave portion being raised by becoming straightened, and consequently reacting from below upwards on the vas deferens, the vessels and all the constituent parts of the spermatic cord, which thus become pinched in a kind of button-hole whenever the man makes any violent effort. I consider it, therefore, very natural that a certain number of cases of acute orchitis may be occasioned by strong muscular action."

In a patient affected with hernia it often happens that a violent degree of inflammatory action takes place in the sac, and that under the influence of this inflammation the reduction of the hernia becomes very difficult, and that symptoms of strangulation even make their appearance. If, in a case like this we succeed, after a prolonged and forcible employment of the taxis, in reducing the intestine, it may possibly occur as a result of the manipulations, that inflammation attacks the testicular cord, that the symptoms do not cease, and that the surgeon, fancying he has not effected a complete reduction of the hernia, performs the operation.

A man has had for some time an inguinal hernia which he has never supported, and which has become irreducible; after an impure connection he is attacked with blennorrhagia, and towards the end of the affection, when the pain in the canal has subsided, and he scarcely pays any attention to the discharge, suddenly experiences pain in the scrotum, and perceives that the tumour, which he has had for a long time, increases in size, and becomes very sensible. One or two days afterwards, the pain he feels is intolerable; there are fever and constipation; hiccough, nausea, and vomiting soon supervene, and he sends for a surgeon, but says not a word to him respecting the urethral discharge, because he imagines that it has nothing to do with his present disease, or because the urethra is no longer painful, or even because the discharge has become suppressed. He tells him that for a long time a tumour has existed in which he hears a gurgling noise; that he has frequently colic, and that it is only since the last few days that he has experienced all the symptoms we have just enumerated. From this description should we not be disposed to believe that all the symptoms are occasioned by the hernia? whereas they are entirely the result of inflammation of the cord. And in this case they would probably make their appearance still more rapidly than in another individual who has no hernia, inasmuch as the ring, already occupied by the displaced intestine, will offer less space for the development of the cord.—*Revue Médical de Beaujon.*

19, Langham-place.

SINGULAR TUMOUR OVER THE SACRUM OF AN INFANT.

Communicated by C. W. CHEBB, Esq., Torpoint, Cornwall.

On the 19th of April, 1847, I delivered Mrs. C. of a fine female child. It was her first accouchement, and perfectly natural in every respect. On my calling at the house the next day the nurse told me that there was something unusual about the lower part of the child's back, which they wished me to see. On examination I found, quite at the lower part of the sacrum, and about an inch to the left of the median line, a fleshy mass about two inches long, and a quarter of an inch in diameter; it more resembled the penis of a child about five or six years old than anything else; in fact, that gives the most correct idea of its appearance; and the resemblance was still further kept up by its having an orifice at its extremity, and a canal through the greater part of its length, although I could not detect that any fluid escaped from it.

Another peculiar feature worthy of notice in this case was, the tumour being frequently re-

tracted to half its length, and this occurred more particularly when the child cried, although the retraction frequently took place independently of crying. It continued much in the same state until the 8th of May, when I passed a ligature round the tumour at its connection with the body, and, May 12, it dropped off, merely leaving a small tubercle, as it were, but this tubercle still possessing the orifice in the centre as the original tumour had, but nothing escaped from it. For the first twelve hours after the ligature was applied the child cried most violently, and would not take the breast; but from that time to the present there has not been a single bad symptom, in fact, the child is thriving most admirably.

I had some hesitation at first about applying the ligature in consequence of the possibility of the tumour communicating with the spinal cord; but, from watching it carefully, I became firmly convinced that such was not the case, and I then determined on pursuing the treatment already recorded, and with the most perfect success.

I am the more anxious to give this case publicity, inasmuch as there are on record the histories of several cases of tumours much in the same situation as, and of a similar character to, the one which I have now related; but in almost all of those with which I am acquainted, on the application of the ligature symptoms of spinal irritation rapidly made their appearance, and the child's life was speedily at an end. And in most of the recorded cases of which I speak, a very small quantity of fluid escaped; in the present case, from beginning to end, there was nothing of the kind; and this mainly, added to some other symptoms, led me to believe that there was no connection between the tumour and the spinal cord, and consequently induced me to apply the ligature.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of May 17; M. BRONNIART in the Chair.

AMERICAN INVENTION.

A letter, dated May 1, was received from Mr. Morton, of Boston, claiming the undivided honour of the first application of ethereal inhalations to operative surgery. The singular tone of the recriminations contained in this trans-Atlantic effusion warrants us in publishing a short extract—leaving, of course, the entire responsibility of the abrupt mode of expression, and of its uncourteous tone, to the proper author:—

"Before I had fully realized the importance of the results of ether, I was advised to associate with me my former instructor in medicine, Dr. Jackson. In an unlucky moment I gave my consent: he was to share the honours—not the emoluments—save ten per cent. on the net receipts. For some time all seemed to go on well. Imagine, Sir, my surprise, when I saw the French papers brought by the February steamer—in those papers, *cet animal engourdi* [we cannot otherwise translate the term but 'that dull beast']—had claimed the whole discovery as his own, not mentioning me in the matter! In November he wrote to his friend M. Elie de Beaumont, saying he had, with the assistance of another, made a great discovery, and wished my name kept out of sight as much as possible. Accordingly, his friend Beaumont took the liberty of striking my name out entirely, &c. . . . As to M. Horace Wells, who also claims the credit of the discovery, his letters to me, before he thought of claiming it, will dispose of him: I have published them in the last number of 'The Boston Medical and Surgical Journal.'

"I have the honour to remain, &c.,

(Signed) "MORTON."

AUTOPLASTIC OPERATIONS IN VESICO-VAGINAL FISTULA, BY M. JOBERT.—In a former com-

munication (see *Medical Times*, vol. 15, 1 344) we related in detail three cases of cure of ancient vesico-vaginal fistula, cured by this operation. The present paper of M. Jobert contains six cases in which it was likewise performed with success. The operative process—now again described by M. Jobert—does not differ from that which we recorded in the columns of the *Medical Times* (January 30, 1847), in an article to which we beg to refer our readers.

ACADEMY OF MEDICINE.

Meeting of May 18; M. BOUILLAUD, V.P., in the Chair.

CAMPHOR.

The commission appointed to report in M. Cottereau's case brought before the academy an amended list of resolutions, which, after a long and confused debate, were adopted in the following order:—

1. M. Cottereau died of pneumonia, and was in bad health a long time before the development of his last illness. 2. Although the pneumonia, gastritis, and cerebral hypertrophy, proved by the post-mortem examination to have existed, cannot be attributed to the agency of the camphor, still it is probable that the prolonged use of camphorated preparations placed the patient in unfavourable organic conditions. 3. With regard to the so-called camphor cures, the academy considers it a duty to guard the public against the dangers of so active a medicine in the hands of unprofessional persons. 4 and 5. That M. Pradagnel receive the thanks of the academy, and that his paper be honourably deposited in the archives.

INTRODUCTION OF STONES INTO THE BLADDER.

M. Lepelletier de la Sarthe, a corresponding member of the academy, related the case of a lady, aged thirty-five, from whose bladder I had extracted, by operation, nineteen calculi formed of pure silicic acid. These concretions had been introduced, according to the lady's own account, which M. Lepelletier fully believed, during somnambulic attacks, and had remained about eight or ten years in the vesica. Their introduction had left no traces, the urethra not presenting any dilatation, and incontinence of urine having been observed. On the surface of the stones a very thin layer of phosphate of lime had been deposited.

M. Nacquart remembered a case of the same kind in a lady, who complained of violent pains in the abdomen. Examination of *per vaginam* betrayed the presence of calculi in the bladder, and so dilated was the urethra that a spoon was introduced, and five or six calculi easily extracted. They were examined chemically by Vauquelin, who pronounced them to be of a siliceous nature.

M. Moreau said that instances of the kind were not uncommon; as to the manner of introduction, doubtless the calculi had been forced into the urethra—most probably not during somnambulic attacks; the narrowness of the duct was explained by the time which had elapsed since the stones had been lodged in the bladder.

M. Lepelletier could not admit with M. Moreau that the stones had been voluntarily introduced: the patient was a woman of the highest respectability, and a nun. (General and prolonged laughter.)

M. Nacquart said that the well-known dilatability of the urethra in women could leave no doubt of the manner in which these foreign bodies had been introduced. It was, in certain women, susceptible of being enlarged to a degree which had permitted the accomplishment of matrimonial purposes in the vaginal cavity.—Meeting adjourned at five o'clock p.m.

HOPITAL SAINT ANTOINE.

CONTRACTION OF THE EXTREMITIES IN A CHILD AGED NINE MONTHS. BY M. GHINOLLE.

The few cases on record of this malady refer to children more than twelve months old. The following instance shows the possibility of the occurrence of the malady at an earlier period.

E. L., a little girl, aged nine months, was admitted into hospital on the 6th of April. The mother, aged thirty-seven, had observed in her other children no symptoms resembling, even in a remote manner, those at present existing. Two months before admission, the infant, otherwise in perfect health, was suddenly seized with contractions of the hands, which lasted nine days without interruption, during which time she continued to take the breast as usual. On the 3rd of April the disease reappeared, the child having been weaned six days previously. When brought to hospital and examined, some slight rhonchi were detected in the chest, the countenance was calm, the shoulders and arms free from any appreciable contraction. The forearms were slightly bent, and both hands strongly flexed on the forearm, almost at right angles. The articulations of the fingers were also partially closed; and on the dorsal aspect of the hand was noticed a scrofulous puffing of the cellular tissue, and a slight redness of the integument. The knees, ankles, and toes were also in a marked state of contraction; oedema of the instep was likewise present, and the muscles of the thighs evidently contracted. It was easy to straighten by a gentle effort the contracted extremities, but the parts resumed their original position when the hand was removed. These attempts caused pain, and no intermittence was observed in the contraction. The pulse was quick, and the skin hot. One grain of tartar emetic was exhibited, but on the morning of the 7th the child expired. On dissection, one anatomical alteration alone was found, viz., considerable condensation and hardness of the spinal cord.

ASCITIS—CURED BY THE IODINE INJECTION INTO THE PERITONEAL CAVITY. BY M. LERICHE, OF LYONS.

CASE.—A girl, aged seventeen, of weak constitution, has regularly menstruated since the age of fourteen, and became affected in the month of January, 1846, with ascitis, after a slight pulmonary affection. Diuretics and drastic medicines had been unsuccessfully resorted to. The circumference of the abdomen measured one metre seven centimètres (three feet eight inches). On the 11th of March paracentesis was performed, and eleven quarts of fluid withdrawn. The following solution of iodine was injected immediately afterwards into the peritoneum (R. Tinct. iod., 3j.; potassæ hydriod., 3j.; aquæ fontanæ, 3viij.). Four ounces only of this solution returned after injection; the remainder was abandoned in the abdomen. The following night the patient complained of some slight pains and borborygmi. The urine was increased in abundance, and on the third day considerable flatulency was observed. Up to March 21, the nights were sleepless, the urine clear and abundant, and great weakness was present; but her strength and appetite returned from that day onward, the abdomen continuing to decrease in size, and a complete cure was finally obtained on March 30.—*Journal de Médecine de Lyons*.

FOREIGN BODIES IN THE BLADDER.

The case reported to the academy by Dr. Lepelletier (*vide* the first part of the present communication), is one which appears to us of sufficient interest, in a scientific and practical point of view, to warrant some further remarks on the subject.

Instances of introduction of foreign bodies into the bladder may be found in Al. Benedictus (lib. 22 de Medend. Morb.) in the Memoirs of the Academy of Sciences (1735); in Morgagni (epist. 42); in Sir Astley Cooper's works, and elsewhere. In the "Descriptive and Illustrated Catalogue of Calculi," contained in the museum of the London College of Surgeons, no less than eleven cases are recorded, with illustrations, of foreign bodies passed into the bladder, and there becoming the nuclei of concretions. Pieces of bone, steel, and silver pins, a portion of bougie, masses of margarine and oleate of lime, resulting from injections of solutions of soap, and the decomposition of the earthy bases of the urine, in combination with the fatty acids of the soap, peas, portion of a tumbler—such are the substances

which occurred after a severe attack of influenza, of six weeks' duration. Six years prior to his fatal illness he had been under the care of Dr. Harrison four months, in the Marylebone Infirmary, and was there tapped for pleurisy, four or five pints of fluid coming away. The aperture was left open, and daily exudation of one or two pints continued for a week; it closed at the end of the second week. Three several times it opened afterwards spontaneously. He went out at the end of four months, and was at work till his last illness. There was observed, on the *post-mortem* examination, general bronchitis of the right lung, with emphysema; the left lung (the tapping having been performed on this side of the chest) was much reduced in size, being fleshy and like spleen in structure.

Dr. Little exhibited a specimen of CARCINOMATOUS TUMOUR, INVOLVING THE UPPER PART OF THE RIGHT LUNG, AND CAUSING ENTIRE OBSTRUCTION OF THE VENA CAVA SUPERIOR, taken from a woman, aged 31, who had suffered from supposed morbus cordis for nineteen months previous to her admission into the London Hospital.

Mr. Prescott Hewett presented five preparations of

RUPTURE OF THE HEART AND LARGE VESSELS, THE RESULT OF INJURIES.

Dr. Peacock exhibited a specimen of LACERATION OF THE AORTA.

A powerful man, 35 years of age, was assisting several others in moving a frame of wood, about ten feet high and six broad, and of about three hundredweight, when a gust of wind overbalanced it, and it fell so as to press him beneath it. He immediately turned deadly pale, gasped a few times, and expired. The exterior of the body displayed no mark of violence, except a slight scratch on the left side of the neck. When, however, the integuments were removed from the front of the chest, the upper part of the sternum, and the sternal ends of the fifth, sixth, and seventh ribs, on the right side, and the cartilage of the seventh left rib, were found partially fractured, so that the whole point of the chest had been depressed. The intercostal muscles between the fifth and six ribs were extensively torn. Some bloody serum was effused into the sac of the right pleura, and the cavity of the left side contained nearly two quarts of blood; much blood was also infiltrated into the mediastina. The blood was found to have escaped from the aorta, which, about half an inch behind the origin of the left subclavian artery, was entirely torn across, so that the ends of the vessel were only retained in apposition by its cellular sheath. There was no evidence of direct injury to the vertebra, or of any part in the neighbourhood of the ruptured vessel. The rest of the organs in the body were natural. Dr. Peacock remarked, that, in the absence of any proof of direct injury having been sustained by the vessel in this case, its rupture could only be ascribed to the violent action of the heart, consequent on the effort to resist the fall of the frame, in the peculiar position occupied by the man at the time. This inference is confirmed by the state in which the heart was found when removed from the body. Both ventricles, but especially the left, were extremely contracted, so that their walls were much increased in thickness, and their cavities entirely obliterated; the organ thus afforded a very characteristic example of the condition described by Bertin as concentric hypertrophy. After, however, it had been macerated in water for two or three days, and the contraction had subsided, the cavities returned to their normal dimensions, and the walls became proportionately thinner. The heart was considerably above its natural size, weighing between eleven and twelve ounces avoirdupois. It is well known, that at the point of union of the obliterated end of the ductus arteriosus with the coats of the aorta, it is very usual that the canal of the latter vessel is found somewhat constricted; and this point is generally, also, one of the earliest seats of atheromatous degeneration. The existence of

these changes at that point, in the present instance, seems to have determined the occurrence of the rupture of the vessel. Elsewhere, the coats of the aorta, though perhaps somewhat thin, were free from disease.

Dr. Hunsley exhibited a specimen of ALVEOLAR (?) CANCER OF THE STOMACH, taken from a patient of Dr. Protheroe Smith, aged fifty-six, who had suffered for five years from an obscure affection of the stomach, and had at several periods had acute attacks, characterized by great hypochondriac and dorsal pain, constant vomiting, and excessive eructation, accompanied with constipation and much febrile disturbance. In the intervals of the attacks, general debility, cough, and uneasiness in the left hypochondrium, nausea in the morning, occasional vomiting, spectral illusions, and habitual constipation, characterized her ordinary state of health. The acute attacks became severe in proportion to their frequency, and the attack from which she died was of a very aggravated form, the hypochondriac pain having extended to the base of the left lung, and other symptoms having supervened indicative of acute pleuropneumonia, the vomiting also being incessant. The *post-mortem* examination was made twenty-four hours after death. The heart was displaced to the right of the median line by the pressure of two quarts of bloody serum in the left pleural cavity, the lung itself being compressed into a small fleshy mass.—Abdomen:—The peritoneum covering the under surface of the diaphragm was of a deep red colour, and much injected. The stomach was firmly attached to the diaphragm by means of an oval lobulated tumour, of the size of a large egg, which was enclosed within the folds of the small omentum, and was closely connected to the lesser curvature of the stomach, extending from its cardiac to near its pyloric orifice. Externally it was covered by the omentum and fat; when cut across, it presented irregular radiating white fibres, dividing its substance into lobuli, containing a yellowish white substance of softer consistence. Portions of the tumour were more dense, consisting partly, however, of adipose tissue. The stomach was of its natural capacity; its mucous membrane, surrounding the cardiac orifice, was extensively ulcerated. A section of the tumour subjected to microscopical examination presented—

1. A granular blastema
2. Numerous nucleated cells and parallelograms.
3. Other cells, nucleated and circular, in clusters, which, from their high refractive power, appeared to contain something analogous to fat.
4. Adipose tissue and oil globules.

The liver was small, pale, and fatty. From the history of the case we may justly conclude that the immediate cause of death was perforation of the stomach through the adherent diaphragm into the left pleura, exciting inflammation of that membrane, and rapid effusion. This, however, owing to the state of distention of the pleura with so much fluid, the unsuspected nature of the case, and the short time allowed for the inspection, could not be positively evidenced. With regard to the nature of the tumour, there could be but little doubt of its being that species of carcinoma described by Cruveilhier under the name of the pultaceous cancer. Though it did not present the jelly-like material contained in distinct pouches, described by Otto as the characteristic of colloid cancer, it approached nearer to that form than to any other.

ROYAL COLLEGE OF SURGEONS.—Gentlemen admitted members on Friday, May 14:—Messrs. Arthur Newstead Holmes, Selway, Yorkshire; Benjamin Button, Hopton, Suffolk; Frederick Gardner, Islington; William John Anderson, Brompton; Francis Cornelius Webb, Stonehouse, Devonshire; John Milner, Harrogate; William Copeman, Coltishall, Norfolk; John Lloyd, Corwen, North Wales; James Miller Shain, Perth, Scotland; and William Ellis, Belfast.

REVIEWS.

On the Pathology and Treatment of Scrofula; being the Fothergillian Prize Essay for 1846. By ROBERT MORTIMER GLOVER, M.D., Corresponding Member of the Medical Society of London; Lecturer on Materia Medica in the Newcastle Medical School. London: John Churchill. 1846.

This truly excellent work, the production of a man of genius and of ability—admitted to be such by his collegiate friends and teachers, and highly esteemed by his seniors in the profession—requires but little commendation from us. As we always anticipated, the medical press universally, we believe, has spoken of Dr. Glover's work on Scrofula in the highest terms; and we feel assured that the profession will be pleased and instructed by its careful perusal. Of a work which should be, and no doubt will be, read by all interested in the progress of pathology, more especially of pathology as investigated by a refined chemical method (applied, we think, for the first time by Dr. Glover), a mere passing notice ought to be sufficient; and to this for the present, from a press of other matter, we shall confine ourselves; but a more laboured analysis is due to the work, and this we promise our readers on a future occasion.

While we quite agree with Dr. Graves, of Dublin, as to the paucity of real results obtained by chemical analysis in the investigation of disease—to which may be added, we think, at present, the positively few real results arising as yet from microscopic research applied to pathological changes in morbid structures—we naturally subscribe also to Dr. Glover's opinion, that (*as yet*) this forms no real objection to the necessity and propriety of pushing these methods to their very utmost. We may not thereby discover a *specific* for scrofula, nor may we advance a single step in our knowledge of the innate nature of this terrible malady; but still the methods must be employed—must be exhausted before we presume to object to them. Problems of the first magnitude, as regards human welfare and existence, remain to be solved: let us be thankful that there are minds so constituted as to trouble themselves with the philosophic solution of such problems. "Henceforth," says Dr. Glover, "morbid anatomy must not be confined to the picture-maker; but chemical and microscopical analyses should form the more important elements of this branch of pathology." It is not much beyond the period of a year, when a remark similar to this, but not so clearly expressed, was made to us by an illustrious pathologist, M. Cruveilhier, himself a great "picture-maker" of pathological specimens. The method, we admit, has failed to a great extent—failed to preserve to the profession trustworthy models of pathological change; still it is a valuable method, and by no means to be despised.

We strongly recommend to *practical men*, as they are called, to read over pages 6 and 7 of Dr. Glover's work: their confidence in "the iodine," "the arsenic," the "black draught," and the "hydr. c. creta," might be shaken with great advantage to the public. Dr. Glover is a rationalist in medicine, and so must every educated and correct mind continue to be until the connection between *practical medicine* and physiological science be proved not to exist, and the whole affair be exploded.

At a very early period the intimate connection existing between scrofula and phthisis pulmonalis came to be observed and admitted; but even the researches of the illustrious Morgagni did not throw much new light on the pathology of scrofula. This is stated, and no doubt correctly, by Dr. Glover. In ascribing to Dr. Matthew Baillie, a Scotsman settled in London the merit of being the real founder of modern pathology, we believe we do him no more than justice. His small work on "Morbid Anatomy" is an immortal work, never to be excelled. From this point, we may notice, with Dr. Glover, the pathology and the treatment of

scrofula. The conflicting evidence on these points is no doubt astounding, and that, too, on matters which one might suppose ought to have been decided centuries ago; but this, we shall find, arises as well from the extreme obscurity involving the essence of the disease, as from hasty observation.

These great points, the Pathology and the Treatment, touch the whole question of every disease: the pathology concerns solely the profession, the treatment the public. What is the internal nature of the disease? says the professional man. What is its cure? says the patient. As regards scrofula, much yet remains to be discovered—much doubt and uncertainty to be removed—much that is profoundly obscure requiring elucidation.

Scrofulous or tuberculous matter is a peculiar morbid formation, the product of a particular modification of the inflammatory process. This is Dr. Glover's opinion, as so expressed in the commencement of Chapter I. It is a practical and good opinion, and has been maintained under various forms by others. The errors to which it may lead in practice, familiar no doubt to most medical men, arise unquestionably from the physician not attending to the words—"Inflammatory process particularly modified." On the grounds logically reasoned, as is always the case with our author, that no very good, or at least all-comprehensive, definition of a *metabolite* could be given by any one, Dr. Glover prudently declines a rigid definition of scrofulous formations. But the following passage, quoted from the work itself, will best explain our author's meaning:—

"Tubercle, in the sense in which the term is here used, includes all scrofulous formations, whether in the lungs, heart, brain, bones, &c., in short, in every conceivable tissue or organ; and we distinguish the scrofulous matter by its microscopic characters, with a certain not very definite chemical constitution, and a physical structure apparent to the eye, and which is well known."—P. 26.

We need not follow the author through his careful and candid critique of preceding and contemporary authors; he agrees in most points with Lugol and Vallee, confirming the researches of these distinguished observers by personal researches; the variety in mere mechanical form, presented by tuberculous matter in various organs, is ascribed to the nature of the tissue in which that matter has been deposited.

The extremely difficult point as to the vascularity or non-vascularity of tubercle, is of course carefully examined in this chapter. We have, for our own part, been always convinced that tubercle is not a vascular body.

Whether tubercle should be ranked among the cell formations, or whether it should be considered beneath this ultimate and essential degree of organization, is a question carefully considered by our author. Its solution, in some measure, must depend on the microscope.

Dr. Carstall, a careful and exact observer, concluded at first against the cell theory *in toto*; and, further, denied to tubercle matter every trace of organized structure. "Tubercle is not a tissue"; "tubercle grows not by intussusception, but more like inorganic bodies." But he afterwards, on reading Vogel's views, recanted, in part at least, his opinions. Upon the whole, Dr. Lebert's opinions seem the best founded—namely, that tubercles present microscopical elements proper to themselves, and distinguishing them from all other morbid products.

Thus it would appear that, as yet, the microscope has failed to give us any clear idea of the essential nature of tubercle; by improved methods future observers may prove more successful.

On the chemical examination of scrofulous products, Dr. Glover's work, as was to be expected, furnishes the most minute and recent, and in so extremely difficult a point, the most exact information. Our limits, confined to a very brief analysis, forbid us entering at any length on this important section.

L'Allemand and Cruveilhier thought tu-

bercles to be merely concrete pus. If by this was meant the ordinary purulent deposits, then most assuredly these distinguished men were mistaken. But, after all, they may be composed of pus *peculiarly modified*. This is not our opinion, but it is one which might readily and consistently enough be mentioned by those who esteem tubercle or tuberculous matter to be the product of inflammation peculiarly modified. Our own observations (not chemical but simply pathological) lead us to think highly of the chemical results to be drawn from the analyses of Prout, Preuss, Boudet, Scherer, Dr. Glover, and others; the following are the general conclusions arrived at by the author:—

"1st. The results of the chemical analysis of tubercle, and its after-products, of scrofulous bones, &c., although they may not as yet warrant very decisive conclusions, yet furnish some useful information, which will be found to bear upon the pathological propositions advanced concerning the essential nature of scrofulous and tubercular affections.

"Thus the large quantity of fat and extractive matters in tubercle has a direct bearing upon the theory supported by many of the advocates of the use of cod-liver oil in the treatment of these diseases. The existence of pyin is important, and could we be sure of that of casein in quantity, we might to a certain extent explain the unorganizability of tubercle. But we have never been able to satisfy ourselves that the protein constituent of tubercle, as examined by us, approaches much nearer to casein than to albumen. Nevertheless, the researches of Preuss, Boudet, Scherer, and others must be held decisive of the existence, at least in some cases, of casein; although the last-named observer is far from confirming former writers in the statement of a large proportion of tubercle matter being composed of this substance. We have made other examinations for casein than those recorded, and have never been able to detect its presence. Whoever considers the very doubtful power of the tests which we possess, for distinguishing these different substances in the animal body, will be very doubtful of the precise nature of the protein basis of tubercle. Nevertheless, we may, perhaps, conclude that there is great probability of this protein compound having a certain approach to casein, or at least of a portion of it exhibiting a tendency to take on the characters of this latter substance. (a)

"2nd. The ultimate analyses which have been made can lead to no very definite conclusion, although Scherer infers, from a comparison of his formulas of lung and liver tubercle, that the difference which exists between them may arise from the substance in the latter situation being less exposed to the air. (b) Thus he says—making the azote the fixed quantity, we have:—

The lung-tubercle ... $C_{43} H_{70} N_{12} O_{13}$

The liver-tubercle .. $C_{45} H_{72} N_{12} O_{13}$

showing an excess of carbon and hydrogen.

"Our analyses would give to the protein compound of tubercle a much smaller per-centage of azote in general than those of Scherer; only 12.31 in the first analysis of mesenteric tubercle, while the proportions of carbon and hydrogen show that the substance had been completely freed from fat. But when we find analyses of normal protein differing almost as much from the ordinary standard, what inference can we draw? Since we wrote as above, Liebig has called in question the protein theory, but the use of the word protein, in this essay, is not hypothetical; it is used to signify a basis of an albuminous or, perhaps, partly caseous nature, which undoubtedly is at the bottom of the constitution of the greater portion of tubercle.

"It does not, however, follow that these ultimate analyses are useless, because we cannot at

(a) From the reviews of the recent work of Mr. Simon, we learn that this writer regards the protein basis of the thymus gland as intermediate between protein (albumen?) and casein.

(b) *Op. cit.* s. 228.

present draw many inferences from them. We see at least the close approximation which they enable us to make between the basis of these morbid formations and protein compounds.

"3rd. The analysis of the concretions which we have made does not bear out in the least the statement of M. Boudet, which makes these bodies contain seventy per cent. of soluble salts. On the contrary, even in the tubercle, which may be supposed to form a transition-stage on the way towards the conversion into the calcareous substance, we find only about one-third of the ash composed of soluble salts; and in the perfect concretion there was merely a fraction of these substances. In this respect our results agree with those of Scherer and Mulder.

"A doubt has arisen, whether these concretions should be regarded as the remains of absorbed tubercle; and this doubt is supported by Rayer, who maintains them to be often the residue of pus. (a) The presence of these concretions may not improbably serve to attract towards them, once formed, more osseous matter.

"4th. The analysis of scrofulous bones requires no comment.

"5th. Scrofulous pus appears to differ from ordinary pus, chiefly in the fluid part being thinner and mixed with albuminous granules proceeding from a decomposition of scrofulous or tuberculous matter. The pus globules appear also, as stated by Mr. Gulliver, to be fewer and less distinct than those of healthy pus. (b) We have found them also more irregular in their form."

The section on the humoral pathology of scrofula abounds, as was to be expected, with discordant views, to which we need do no more than advert; the examination of the bile, lymph, chyle, and stomach secretions in scrofula occupies about twenty-five pages of the work. Some important questions are here considered, and various hypotheses set aside on what again to be sufficient grounds. But the occurrence of tubercular matter in the lactals and mesenteric absorbents apparently is an important fact which admits not as yet of any satisfactory explanation.

No particular affection of the urine was detected by Dr. Glover.

The brief analysis offered of the first and second chapters of this excellent work will suffice, we trust, to convince our readers of the extremely careful manner in which the author has examined each point of interest. Chapter III. is on the scrofulous diathesis; some of the practical men who jump to conclusions should peruse this chapter carefully. The comparative pathology of scrofula is discussed in Chapter IV.; and in the following chapter is discussed the identity of scrofulous and tuberculous diseases. But here we may conclude by venturing to assure our readers, that as well in these as in the subsequent chapters on the essential nature of scrofula—the etiology—the treatment—no important topic has been left untouched by Dr. Glover.

The work does much credit to author and publisher, and cannot fail to be always esteemed, whatever discoveries may hereafter be made on the nature and treatment of this terrible malady. We, with every confidence, recommend this philosophic and original work to the most favourable notice of the profession.

The Treatment of Strictures of the Urethra by Mechanical Dilatation, &c. By JAMES BRIGGS, Senior Surgeon to the Lock Hospital. 8vo. London: Longmans. 1845; pp. 62.

A very sensible summary of our general knowledge on this important subject. It is one which has clearly engaged much of our author's attention, and that attention has evidently not been bestowed in vain. Many valuable suggestions flow through the pamphlet, and many judicious references are scattered amongst them. Mr. Briggs is well at home both in the practical and literary part of his subject.

(a) "Archives de Médecine Comparée," Nos. 4 and 5, p. 203. 1843.

(b) *Op. cit.* Explanation of plates, p. 62.

The instrument which he advises in cases of stricture of the urethra is a steel sound, so shaped as to combine the advantages of the wedge and the lever. Thus he considers to be preferable to the ordinary sounds or bougies in common use.

"By giving an obtuse edge to the cone of the instrument, which by the flattening of the two sides is nearly triangular, less resistance is made to its passage through the stricture, and a dilatation of the part is far more readily effected than by the mere conical sound, and more especially in the denser kinds of stricture, the removal of which cannot be effected without great perseverance in the ordinary and tedious process of treatment by the common bougie.

As a steel instrument admits of a high degree of polish, it passes with far more ease to the patient than a bougie, can be guided with more certainty to the contracted portion of the canal, and the point so directed as to act successively on any part of the canal in the line of its axis, where the constricted part, as most frequently happens, is seated at the curve of the passage, the weight of the handle alone acting as the long arm of a lever, greatly increases its mechanical power, and makes a more uniform and steady pressure on the part to be dilated than any force applied to it by the hand of the surgeon. It is also more easily withdrawn, and with less pain to the patient, where it has been grasped by the stricture and allowed to remain in the passage for some time, than the common or cylindrical sound. (Jⁿ 31, 32)

The further observations of our author on strictures of the urethra, and their attendant affections, on fistulous openings, encuresis, and retention of urine, display the researches of a very practical mind, and 'are well worthy of perusal.

TO CORRESPONDENTS.

THE MEDICAL TIMES.

SATURDAY, MAY 29, 1847.

THE HOUSEHOLD INQUEST, AND POSITION OF THE MEDICAL OFFICERS OF THE SERVICE BEFORE CORONERS' COURTS

In last article we adverted to the suppression of the evidence of Captain Shirley and Private Rising. We showed that their testimony -

though important—was suppressed not only *judicially*, but through the public journals. and, while we hunted how much the double suppression helped to raise—to propagate and maintain a gigantic delusion, invited an explanation of the extraordinary circumstances. We have yet had none—it may be feared we shall have none. We come now to other circumstances in Dr. Warren's charge just as strange, and which, following his affidavit, we shall dispose of just as briefly.

Pending the inquest, instructions were sent to a barrister in the Temple to draw up a formal verdict in anticipation of that of the jury. The barrister's name being mentioned in the affidavits which were submitted to the court by Dr. Warren's counsel, we can have no hesitation in announcing that he is the eminent Mr. Peacock, of Raymond's buildings. Mr. Peacock declined the fee, and refused to draw the verdict. At the bar, of course, there is but one opinion of the propriety of that refusal.

Shall we indicate the nature of the verdict? It is done when we mention that the jury, on the last day of the inquest during a mid-day adjournment—here sipped over their drunken cups to strangers, with whom they were allowed to drink and discourse, that on returning to their box they would give a "stun" verdict, and that then a "stun" verdict "would be either murder or manslaughter."

So much for the appearance of so much for the sober impartiality of the coroner and jury. One word on the evidence given. During the third sitting, there was a small delay adjournment for respectment. It was at spent. Matthewson and his party had been previously examined, and the jury as well as the witnesses had been called in question. This men, the jury spent the adjournment in private room with the coroner and his duty in a day, being, picture and on the morning of the inquest the jury were in the witness box. What took place? What was said? What was promised?

With you is a / / witness though
his character and the money were both im-
paired hence I am patronized by the judge
in all the examinations I need he is honoured
by the judge with a private consultation hence
he is opposed by the judge at public meetings.
hence money or money is got up for him by the
judge and hence, finally, after the inquest, the
coroner takes all the trouble to reach Hounslow,
in order to see his witness, and hand him over
money and time. Such are the things which
an English judge may do for a useful witness of
indifferent repute.

A thousand facts and conclusions and condemnation attend every moment's further attention to this case, but digust withholds us from that further and thorough investigation which, now inevitable elsewhere, cannot but remove from the child's seat of justice its most glaring as well as its foolhardy of deprecators. Society would, indeed, be brought to a strange pass by the dandyish virtue of our time, if such enormities are to receive from our legislators no worse rebuke than would become the utterance of a false quantity, or the breach of a grammatical concord—viz, suppressed laughter and quiet contempt.

THE COLLEGE OF SURGEONS AND ITS CLIENT

The Councillors of this ill-tuned club have begun the work of purgation. They have cleared

There are two classes of persons who deserve

On the first of the insult offered to the members of the church, I was in Liverpool, and at the next I visited him on sufferings, in my day, he returned him at the conclusion of the churchman. It certainly is not a fact that his professional activity gave way and the general decline in it neither does it appear that he offered an appropriate and dignified rebuke to the religious his boldness in conduct. He was not a man who must have understood that the church was not at the expense of pauper relief and general philanthropy, and he was in duty bound to once to express it. Though the workman was a Methodist, it did not make her less an object of compassion, but offered an additional motive force, if possible, her life, in order that he might have true given her for repentance. Charity inquires not first into the causes of suffering, nor are its efforts proportionate according to supposed desert, but, a strong to evil thoughts, it is prompt in the performance of good actions. If reverend gentlemen are to secure the affections of the poor,

he luckily show'd his art,
 In a rich fold dough to make savoury tart,"

we are enabled to declare, that this one thing is certain, that in the month of May, 1845, he shut up his pastrycook's shop, and journeyed up to the metropolis with the laudable intention of metamorphosing himself into a surgeon. Here he waded for him through an hospital, attended lectures, received abundance of cramming, and, having examined the council of Lincoln's-inn files, he presented himself before the College examiners, and forthwith they send him out with their red dubtable paper, by which all men were to know that he was fit and capable of exercising the art and science of surgery. Armed with this valuable document he retraced his footsteps to the town of Taunton, where he now physicks the inhabitants with the infinitesimal doses of homoeopathic medicines. Here, doubtless, the elegant pastrycook esteemed himself as safe under the protection of the College diploma as Achilles did behind his celestial shield. The surgeons, however, upon whose dom he intruded, while they were filled with astonishment at the rapidity of this metamorphosis, resolved, if possible, to pluck him of his diploma. Accordingly, they addressed the ruling powers of the College in London, representing the scandal which the circumstances were calculated to produce, as well as the extreme hardship to those members who, by the regulations of the College, had been obliged to go through a lengthened period of regular study, and a great deal of expense, in

order to obtain a diploma which had been granted to a retail shopkeeper after a period of only on year of alleged study, and at a comparatively trifling outlay of money; and, further, called upon the authorities to prosecute inquiries into the testimonials and certificates produced by Mr. Blake, before the court of examiners, as should place the matter in a position satisfactory to all concerned in upholding the honour and credibility of the College of Surgeons.

In due time an answer was returned with a list of all the certificates which the candidate had presented, and the additional discovery was made that the ruling powers had broken their own laws in order that more sovereigns might be added to their coffers, and another member enrolled in their books. The Taunton surgeons having now got Messrs. Lawrence and Co. into a corner, there it was determined they should be kept till they had eaten their own words by recalling the letters testimonial which the pastry-cook had received. This they at length did in a very humble manner, by requesting Mr. Blake "to return the diploma granted him, he having ceased to be a member of the College."

Ever watchful over the interests of the profession, we announced some time ago the insult that had been offered to its members by this disreputable transaction; and, though a certain pseudo-reformer shortly afterwards endeavoured to call our veracity in question, it is now placed beyond all doubt. This is only one case among many others which go to prove how very easily the College testimonial may be obtained. Some years ago we knew a young Frenchman who came over to this country in order to procure the English surgical diploma. He furnished himself with proper certificates, and in addition was a diligent attendant at two or three grinding-shops. There was some defect about his intellect, however, which made even the grinders despair of his success. Up to the College, however, he had determined to go, and at the appointed day was accompanied by some of his fellow-students, who waited outside the doors, curious to know his success.

After a time the little Frenchman made his appearance, triumphantly flourishing the surgical diploma; and when the astonished pupils asked him how he got through his examination with so much success, he laughingly replied, "When they put a question to me which I could not answer, I spoke French to them!"

We talk about reform, and we feel its necessity; let the pastrycook's diploma teach us where we must begin. The College of Surgeons is not like its own laws—made to be altered; but like those of the Medes and Persians—unalterable. It becomes the surgeons, therefore, in general practice, to seek a new incorporation for themselves, if they hope to retain their respectability. Let no fuss about registration draw them away from this one object. It is that upon which their eyes must be ever fixed, and towards which their energies must be constantly directed: its attainment is then certain; and, once secured, future good legislation will be no difficult matter.

WHAT IS THE VALUE OF REGISTRATION?

TO THE GENERAL PRACTITIONERS OF MEDICINE, &c.
GENTLEMEN,—I apprehend that the large mass of the general practitioners, are in agreement with the Council of the National Institute in reference to the destructive effect of the Registration Bill

on their particular interests. Two or three dissentients, only, have had the temerity to raise their feeble voices against the decision of this Council, though I am sorry to observe that there are many who, unable to refute the justice of their objections, nevertheless pursue a different policy, and thus exhibit in themselves lamentable examples of the sacrifice of honourable principles to assumed personal advantages. These men are few in number, but they must be answered, and, if possible, reclaimed. I do not allude to the members of the National Institute, who have, I believe, almost unanimously, adhered to their original principles, but to those men who have at earlier periods been the loudest declaimers in favour of particular objects, and are now prepared to discard them for others more suitable to their present feelings or purposes.

Let us confine ourselves, gentlemen, to the simple question of registration, and trace out the results that are the necessary consequences of its operation. I can remember, and I believe that some of the most active members of that highly independent body, the Medical Registration Committee, can remember also, that the *Medical Protection Assembly* was called into existence by the grant of an unjust charter to the College of Surgeons.

The *representative principle* was the soul of that movement; the profession felt then, as they know now, that they have no barrier against oppression, no resource against injustice, except in the full operation of this principle in the government of our corporate institutions. That movement failed because it was a body without a head, or because the head it had was more interested in its ruin than in its success. Mr. Wakley held that docile flock by a short tether, or gave them just rope enough to twist a noose round their own throats.

All these men, however, with Mr. Wakley as their leader, are compromised to this principle: whether it be Mr. Ross of the National Institute, Mr. Simpson of the Registration Committee, or Mr. Lynch of Common-Council fame, all are pledged to the achievement of this great end—*independence and self-government in relation to our corporate institutions.*

Now, gentlemen, some of you are reviling the Council of the National Institute because they oppose a bill that will confirm the hateful charter which you have heretofore so indignantly denounced, and because they contend for a principle to which you are the unworthy apostates! It is natural, very natural, but not the more honourable on that account. We can comprehend the animity, but we cannot understand the folly that discloses it. "Hope deferred maketh the heart sick;" and it is probable that, like the fox in the fable, you are sick of watching what you cannot seize: you now pretend to despise it, but you are resolved in your hearts that, since you could not appropriate the boon, it shall not be the prize of another. You are prepared, like rival lovers, most cordially to detest the successful suitor.

Let me ask the question of any candid man, if the Council of the National Institute is to be guided rather by the treacherous and uncertain counsels of these incoherent declaimers, than by the consistent and avowed principles on which it is established, and by which it has been governed? Is the policy of the Institute to veer about in accordance with every fleeting gust of public folly, or to pursue a direct course to its declared end? Amidst all the shiftings, the vicissitudes, and the contentions of public

opinion, the National Institute will, doubtless, be true to its principles, and stand at last a beacon to guide us to the only rational, the only probable, object of our attainment.

Again, gentlemen, there are many licentiates of the Society of Apothecaries who imagine that by means of this bill they shall redeem the unconditional privilege to hold appointments in poor-law unions which they possessed prior to the passing of the Poor-law Amendment Act, which most shamefully robbed them of their purchased right; and also to hold offices as surgeons in public institutions where now a surgeon alone is eligible. I regret the duty that compels me to dissipate this delusion. It is true that the bill proposes to enable every qualified man to practise in all branches of the profession; but, then, look at the *CERTIFICATE* of the Registrar, and what are you denominated?—*An apothecary!* You, as an apothecary, can already practise in every branch of the profession, and break no law; and you expect that the privilege—the honourable distinction of registering as an *apothecary* will qualify you to hold a public appointment as surgeon! The first surgeon that competes with you, although probably not otherwise equally qualified, will infallibly drive you from the field.

Nay, gentlemen, you will be constituted an inferior class—the *lowest class* of general practitioners of medicine. The surgeons will stand above you in public estimation, and the practitioner who can produce no other evidence of his qualification but a degree, acquired with too much ease to be honourable, will establish his respectability upon the ruin of yours. The pure licentiates of the Apothecaries' Society in this country are upwards of 4000; if they consent to this degradation, they will deserve it.

But what are we to think of the individual who thus knowingly and deliberately, in violation of all his former pledges, and in contempt of all the professions of his previous life, can devise, publish, advocate, and force on a scheme that will infallibly degrade, stigmatize, and injure one half of the large body of educated gentlemen whom it pretends to serve? Nothing but the most subtle and persisting malevolence could have dictated such conduct towards men who have been guilty of no other crime against him save that of helping him to his character, and establishing his fortunes. I leave it with his own conscience to decide whether this be a crime or not. If it be, the members of the profession have certainly been unwitting accessories.

Every lie, gentlemen, told in every shape which the subject of Medical Reform will admit of, has been, at various times, published by this person; and you have no greater reason for trusting his asseverations now than you had at any former period.

It is a thankless, nay, a painful, duty for any lover of truth to denounce thus boldly the character or conduct of any individual; but there are times when inclination must be sacrificed to duty, and, however repugnant to our feelings it may be, when obnoxious individuals must be sacrificed to truth. Many, nay, all of you, may say—"But this is not necessary now—we know Mr. Wakley to be habitually mendacious, and we do not trust him. We exercise our own judgments in this matter." Upon the merits of the question, then, let it be tried.

Is it desirable that the *general practitioners* of this country shall continue to be divided into

three grades, and that these grades shall be confirmed by an act of Parliament? When the Council of the National Association first contended for a separate Charter of Incorporation, a great outcry was raised against the scheme because, forsooth! it would establish a *third grade* in the profession! How many grades, think you, this bill will establish? They will be so numerous that I cannot possibly designate them; but, practically, the general practitioners, alone, will be separated into the highest grade—the graduates of the Scotch Colleges;—the middle grade, the members of the College of Surgeons;—and the lowest grade, the licentiates of the Apothecaries' Society! Your advocacy of this bill is certainly remarkably consistent. Your intelligence is as discriminating as your simplicity is amiable. It is gratifying to see such a confiding facility of disposition, such an obsequious reverence for the assurances of others, and such a graceful propensity to be cajoled into meannesses or folly. Oh! but the regular practitioner will be distinguished from the impostor! Verily, this is a sugarplum that would charm any naughty boy into good humour. It is, without doubt, the most irresistible of arguments. A little wheedling will soften the most obdurate pertinacity. Many a poor sparrow has been caught by birdlime far less adhesive in its properties than this. Registration may be a very good bird-call for young sparrows, but the old birds distinguish too readily between the false note and the true one.

Put the question to yourselves fairly, gentlemen, and answer me whether any one of you is prepared to give information and carry on a prosecution against an individual who may be illegally practising, at this moment, in your own neighbourhood? The Apothecaries' Act is now rendered efficient for conducting such prosecutions in a summary manner. The expense and trouble are so trifling that I apprehend the new bill in this respect will have little or no advantage over it, and yet how few licentiates of the Hall will care to put in force the law which is their protection. They can do it at this moment, they do not do it, and they will not do it more energetically under a new law.

Under the proposed bill the whole responsibility of prosecuting offenders will rest with the individual qualified practitioners themselves; under the old law a corporation as well as the members of the profession in their individual capacity, can act upon its provisions, and yet how great is the disinclination to incur the risk and annoyance of a public prosecution! There will be found to be a great defect in the practical working of this bill; and I conceive that its advantages in reference to the power of punishing offenders have, under all the circumstances of the case, been greatly overstated.

There are, however, a great number of gentlemen now understood to be unlawfully practising, although possessed of an educational qualification, who would doubtless feel more at ease if they were legally recognised, and could practise in England without risk, question, or demur. This I believe to be the gist of the argument in favour of this bill. But consider, gentlemen, many of you have been practising in this manner for twenty or thirty years; no one has hitherto interfered with you, or prevented your getting handsome practices, and acquiring considerable reputation. Do you suppose that there is any immediate danger to your interests? Surely not. Are you, then, prepared to sacrifice the respectability and welfare of your profession to the ac-

quisition of a small boon for yourselves? I am quite satisfied that not one of you would have ventured to recommend so unjust and pernicious a proceeding, and now only support it because an individual less conscientious, and more inimical to the interests of your class, has had the audacity to propose it. There is no necessity for this indecent hurry to acquire a right that will be of comparatively little positive advantage to you when you have gained it.

I do not deny the expediency of a general system of registration: it is a necessary component part of any useful measure of Medical Reform; but it must follow, not precede, the recognition of those fundamental principles which are the very vitals of the question. Are you bond or free? The registration will either fix the brand of your servitude, or seal the record of your manumission. You must acquire your rights and establish your principles before you can consent to the passing of a law which shall for a century, perhaps for ever, either confirm or destroy them.

The Medical Registration Committee are labouring assiduously to promote this measure: their efforts must be futile, because they have no lever for their operations but that selfishness which their most ardent followers would be ashamed to acknowledge. They are also men of low mark in the profession: the tainted members of other dead bodies—the mere cannon of professional agitation, galvanized by the secret agency of the member for Finsbury. They are the mere puppets of his will: the showmen of the new legislative monster, by which the honourable proprietor hopes to enrich himself. They exist only on his weekly allowances; and I have no doubt would have no objection to continue their board wages immediately a suitable board can be established to receive them. If this bill receive support, let it be through a committee appointed by the masses of the profession; but this is chimerical. No sensible man would lend his aid to promote such an end.

I have at various times, gentlemen, conjured you to stand by the Apothecaries' Act—I do so still—for I have no faith in Mr. Wakley's ability to carry his bill, with its prohibitory clauses unimpaired, through the House; and if he, for the sake of the honour of passing a measure of this kind, should consent, in committee, to the relaxation of his restrictive clauses, we might find ourselves, when the bill is passed, in a far worse position in reference to our ability to repress illegal practice than we are at this moment. I honestly believe, too, that he would suffer an amendment (to speak in parliamentary language) of these clauses for the privilege of passing his bill; and no man of ordinary judgment who knows his character can believe otherwise. What then, gentlemen, would be your position? You might exclaim against the deception; and we, if we were not also sufferers with you, might laugh at your credulity. But this would be a very sorry satisfaction.

Although I still call upon you to defend the Apothecaries' Act, I by no means desire you to defend the Apothecaries' Company. The general practitioners owe nothing to corporations, and acknowledge none. Let them be independent. It may be desirable at some future time to make that rotten fabric resound with the protest of the profession: and when this happens, it must fall. The members of the College scorn it; their own licentiates despise it. The corporation has not been able to achieve a character for itself; it has elevated the profession, but has failed to

raise its own respectability. For the present, enough.

I have the honour to be, Gentlemen,
Yours, very faithfully,
VOX VERITATIS.

LETTERS TO THE MEDICAL PROFESSION OF THE UNITED KINGDOM.

LETTER II.

GENTLEMEN,—Since I had the honour of last addressing you (a), I have received, from various parts of England, Wales, and Ireland, communications expressive of the cordial approbation of their respective writers, and conveying the most liberal offers of co-operation and support in the great work of charity, to the execution and complement of which my life and its best energies are henceforth to be devoted. Gentlemen distinguished by superiority of intellect and attainment, both within the pale of our profession and unconnected with it, have testified their warmest approval of my project, and honoured me with their names as subscribers to my intended literary work.

Since the letter to which I refer was written, several afflicting instances of the widows and families of medical gentlemen, left in a state of indigence or almost utter destitution, have come within my knowledge, and given a fresh impulse to the efforts which I am making to wipe off this dark stain from the character of our noble and otherwise beneficent profession. I have, also, established a correspondence with the accomplished and philanthropic Mr. Daniell, of Newport Pagnell, from whose experience and enlightened views I calculate upon deriving the most substantial aid and information in the prosecution of my labours; and I have written, with my own hand, to almost every gentleman of our profession in the United Kingdom with whom I have the pleasure of being personally acquainted, or connected by literary ties.

Whether my project will be amalgamated with that of Mr. Daniell, or whether it will assume and retain a distinct form in connection with his plan, a few days will now determine. Meanwhile, I beg leave to submit to the consideration of my professional brethren the following outline of my own project:—

1. Any regularly-educated medical practitioner in possession of his ordinary health and intellectual faculties shall, by the annual payment of two guineas in advance, be entitled to the annual receipt of one hundred and four pounds in the event of his being disabled by age, bodily or mental sickness, or infirmity, or accident, from the prosecution of his professional labours, and his bringing forward satisfactory evidence that he possesses no other source of income or emolument. If he possesses any income less than one hundred and four pounds annually, the deficiency shall be made up to him from "THE MEDICAL FUND."

2. A regularly-educated medical practitioner, by the annual payment of two guineas in advance, shall, on his decease, obtain for his widow the annual income of one hundred and twenty pounds, which shall be regularly paid so long as she may live, require it, and remain a widow. If she possess a smaller income, she shall be entitled to receive only such an annual sum as will make up for the deficiency.

3. A regularly-educated medical practitioner shall, by the annual payment of one or two guineas in advance, secure to one or two of his children, on his decease, the annual income of forty-five pounds each. To the annuitant, if a boy, the money shall be paid until he shall have attained the age of twenty-five years; if a female, so long as she may require it, and remain unmarried.

4. Any lady or gentleman, whether connected with the profession or otherwise, may, by the annual payment of from one to six guineas in

(a) See *Medical Times* for Saturday, April 3, page 121.

advance, procure for a superannuated or disabled regular practitioner of medicine, or the widow and children of a deceased practitioner, the same advantages, in proportion to the sum annually subscribed, as will accrue to the practitioner who himself subscribes with the laudable view of making provision for his own person and family, in the season of adversity and the hour of death.

Such is an outline of the comprehensive and munificent plan whereby I hope, with the cordial co-operation of my medical brethren, and of the more opulent and enlightened friends of our neglected profession, to make a permanent provision for its less fortunate yet deserving members, their widows and orphans. Many of the minutest details of my plan remain to be explained; these will constitute the subject of a future letter or letters.

That, by the means which I have here indicated, all the great and beneficent objects in view may be fully carried out, I am quite prepared to prove; especially if the good cause be zealously espoused by the more distinguished and wealthy members of our own profession; and I shall be enabled by the steadfast sanction and support of all grades and classes of our profession, in the prosecution of my literary projects, to contribute a few hundred pounds annually to the "MEDICAL ANNUITY FUND," which I am thus seeking to establish.

I have the honour to subscribe myself, gentlemen, your friend and fellow-labourer,

SHIRLEY PALMER, M.D.

Birmingham, May 24.

P.S. The prospectus of a series of medical works, the emolument of which will be devoted to the augmentation of the "MEDICAL ANNUITY FUND," is now in progress of distribution. By any gentleman who may not have received a copy, or feels desirous to assist in its distribution, any number of these prospectuses may be obtained, on application to myself, or my son, Mr. Charles Ferrers Palmer, surgeon, of Birmingham, or Mr. Edward Fielding Palmer, surgeon, Tamworth.

THE DIPLOMA OF THE COLLEGE OF SURGEONS OBTAINED UNDER FALSE REPRESENTATIONS.

The Taunton and Somerset Branch of the Provincial Medical and Surgical Association, having discovered that a Mr. James Dore Blake had obtained the diploma of the College of Surgeons by improper means, brought the matter before the Council. It appears that Mr. Blake had been for thirteen years prior to May, 1845, a retail pastrycook, and that after one year of medical study he presented himself at the College of Surgeons, London, for examination, and obtained their letters testimonial as to his fitness to practise. The council, after considerable delay, sent the following resolution to Dr. Woodforde, the president of the branch association:—"At an extraordinary meeting of the council of the Royal College of Surgeons of England, Tuesday, the 27th of April, resolved, 'That it appears to the council that Mr. James Dore Blake obtained his examination and letters testimonial by false statements and imposition; and the council does, therefore, recal such letters testimonial, and hereby declares the same to be void; also, that Mr. Blake be requested to return the diploma granted to him, he having ceased to be a member of this college.'—EDMUND BELFOUR, Sec."

CENTRAL CRIMINAL COURT.—MAY 13.

OLD COURT.

(Before Mr. Baron Alderson.)

Michael Sweetman was indicted for a misdemeanour, in having unlawfully practised as an apothecary, without having undergone the required examination, and obtained a license from the Apothecaries' Company.

Mr. Clarkson appeared for the prosecution, Mr. Ballantine and Mr. Huddleston for the

The defendant, who surrendered, pleaded guilty to the indictment.

Mr. Ballantine said that he felt he had no answer to make to the charge on the part of the defendant, and he could only inform the court that there was no imputation upon his moral conduct, or of unskilfulness; but still he had, no doubt, infringed the law, and the Apothecaries' Company were perfectly justified in adopting the present prosecution. With these remarks, he must leave the defendant in the hands of the court.

Baron Alderson said he believed this was the first prosecution of the kind.

Mr. Clarkson said it was, but he thought it right that it should be publicly known that it was the intention of the Apothecaries' Company to prosecute in future in every case, as they were determined to put an end to the system of unauthorized and unqualified persons acting as apothecaries, as such a proceeding was calculated to do great injury to the public.

Baron Alderson said the offence, no doubt, amounted to a misdemeanour, but, as this was the first prosecution of the kind, the justice of the case would probably be met by the defendant entering into recognizances to appear and receive judgement, if he should be required to do so; and if he refrained from carrying on his calling, or obtained a legal license to enable him to do so, he would probably hear no more of the matter.

Mr. Ballantine said that the defendant was anxious he should state that he had pursued a regular course of study for the profession in which he had been engaged, and he would have taken out a license, but that circumstances had prevented him from doing so. He would now, however, immediately take the necessary steps to pass the required examination and obtain a license.

The court then ordered the defendant to enter into his own recognizance in £100, and find two sureties in £50 each, to appear and receive the judgment of the court, if he should be required to do so.

GOSSIP OF THE WEEK.

THE LONDON HOSPITAL.

The annual distribution of prizes and honorary distinctions awarded by the medical officers and lecturers at the conclusion of the winter session took place on Thursday afternoon in the hall of the hospital, in the presence of a large body of governors and friends of the school, when the following were awarded—viz.,

Two gold medals, presented by the governors to pupils for zeal and humanity in attendance on the patients—in the medical wards, to Mr. Squire Sprigge, of Suffolk; in the surgical wards, to Mr. William Foot Vidal, of Aveley, Essex.

Anatomy.—Two dresserships (value 25 guineas each), to Philip William Govett, Plymouth, and Frederick Edward Goldsmith, Bedford.

Practice of Medicine.—Gold Medals: George Climmenson Day and John Rygate, London. Silver Medal and Books: Edward Haycock; Charles William Latham, London. Honorary Certificates: Thomas Nadauld Brushfield, London; and John Cooper, Stratford.

Chemistry.—Senior Class.—Gold Medal: Thos. Nadauld Brushfield, London. First Honorary Certificate: Alonzo Henry Stocker, Shrewsbury. Second Honorary Certificate: Frederick William Pearce Jago, Bodmin. Junior Class.—Silver Medal: Samuel Reynolds, Debach, Suffolk. Honorary Certificate: Edward Foott, Droghmore, Cork.

Materia Medica.—Gold Medal: Frederick Wm. Pearce Jago, Bodmin. Honorary Certificate: Charles Harper, Plymouth.

At the conclusion of the distribution, Mr. Hambury, the treasurer of the hospital, in an excellent address, complimented the fortunate competitors upon their success, and, whilst holding them up as examples to the other pupils, encouraged them to increased exertion in their honourable professional career.

MIDDLESEX HOSPITAL SCHOOL OF MEDICINE.

DISTRIBUTION OF PRIZES, May 22, 1847.

Francis Hawkins, M.D., in the chair.

Medicine.—Prize, Mr. S. G. Bousfield.

Surgery.—Prize, Mr. W. B. Clapham.

Anatomy.—Prize, Mr. Charles Pates.—Certificate, Mr. Arthur Smith.

Pathology.—Prize, Mr. S. G. Bousfield.—Certificate, Mr. W. B. Clapham.

Practical Anatomy.—Prize, Mr. C. Pates.

Materia Medica.—Prize, Mr. Charles Hayman.—Certificate, Mr. Joseph Sims.

Midwifery.—Prize, Mr. S. G. Bousfield.—Certificate, Mr. E. B. Passmore.

Certificate for Practical Midwifery.—Mr. A. D. Home.

Forensic Medicine.—Prize, Mr. W. B. Clapham.

Botany.—Certificate, Mr. W. G. Haytor.

Theological Prize.—Mr. Augustus Grant. Honorary Certificates for Regular Attendance and General Good Conduct.—Mr. Bousfield, Mr. Clapham, Mr. Davidson, Mr. John Day, Mr. Fearon, Mr. Hayman, Mr. Pates, Mr. Sims, and Mr. Woods.

Certificates have also been granted to the following Gentlemen, for Regular Attendance and General Good Conduct, during the Session 1845-46.—Mr. Bousfield, Mr. Boyers, Mr. Clapham, Mr. Day, Mr. Grant, Mr. Home, Mr. Smith, and Mr. Tomkins.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary examinations, for the diploma of this college, were admitted by the Court of Examiners members of the institution, on Friday evening, the 21st inst., viz: Messrs. R. P. Bayley, Broadstairs, Kent; W. H. Bruce, Bath; H. Tireman, York; R. Bentley, Hifehim, Herts; J. F. O'Leary, Cork; H. W. Slack, Liverpool; A. Somers, Dublin; G. A. Wilkinson, Bishopwearmouth, Durham; W. B. Deacon, Market Deeping, Lincolnshire; J. Ward, Sunderland, Durham; and R. N. Bower, Chelsea.

NAVAL APPOINTMENTS.—Assistant-Surgeons: Dr. Archibald Armstrong, Frederick Manger, and Henry Mathias, to the Caledonia; William Calhane and James Wood, to Plymouth Hospital.

MORTALITY TABLE.

For the Week ending Saturday, May 22, 1847.

Causes of Death.	Total.	Average of 5 Winters.
ALL CAUSES.....	911	914
SPECIFIED CAUSES.....	911	909
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	199	106
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat.....	90	99
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	148	158
Diseases of the Lungs, and of the other Organs of Respiration.....	237	276
Diseases of the Heart and Blood-vessels.....	36	29
Diseases of the Stomach, Liver, and other organs of Digestion.....	87	70
Diseases of the Kidneys, &c. Childbirth, Diseases of the Uterus, &c.....	12	8

COURSE OF LECTURES ON CLINICAL MEDICINE.

Delivered in the THEATRE of QUEEN'S COLLEGE, Birmingham.

By SAMUEL WRIGHT, M.D.,

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Cuvierian Natural History Societies of Edinburgh, &c.

Rheumatism; divisions of it into acute, subacute, and chronic; acute rheumatism; symptoms; characteristics peculiar to it; the parts upon which it seizes; its metastatic tendencies; products of its inflammatory action; exceptions to these; illustrations; acidity of the secretions; two pathological points to be regarded in the treatment of rheumatism—inflammation and acidification; neither to be pursued exclusively; comments; observations upon the alkaline treatment of rheumatism; not a specific form of treatment, but still valuable; illustrations; comments; why soda is generally preferred; when potash should be chosen; general observations.

GENTLEMEN,—During the past six months we have had some severe but very successful cases of rheumatism in the hospital. In this lecture, and the succeeding one, I shall discourse to you concerning this troublesome ailment and the treatment of it.

Rheumatism shows itself in a great variety of forms, and sometimes rather anomalously; this fact has suggested to those who are fond of minute distinctions, to classify the varieties I speak of, and make a somewhat formidable list of them. I have never been able to see the value of this, but I have often seen its disadvantages, in perplexing the mind both of the student and the practitioner.

The most convenient division of rheumatism, and that which seems to be most consistent with sound pathology, is into *acute, subacute, and chronic*. The first of these will constitute the substance of to-day's lecture; the others will furnish our topic when we next meet.

Acute rheumatism, known also by the name of inflammatory rheumatism, and by that of rheumatic fever, when general febrile symptoms co-exist with local derangement, is a disease essentially inflammatory in its nature. This is the first light in which we have to view it. The parts which it attacks are, during its manifestation, marked by redness, increased heat, swelling, tension, tenderness, pain—especially on pressure or motion, a congested state of the bloodvessels, and accelerated circulation through them. These are the features which the inflammation of rheumatism possesses in common with inflammation in ordinary. It possesses, however, certain characteristics peculiar to itself and to its pathological ally, gout.

These are, 1. *The Structures upon which it seizes.*—Rheumatism generally visits the ligamentous tissues; the sponneurotic coverings of muscles

(more rarely muscles themselves); tendinous sheaths; cellular investments of joints; and envelopes of nerves. It is inflammation of this structure surrounding the sciatic nerve which constitutes the painful ailment known by the name of sciatica.

2. *The Metastatic Tendency of the Inflammation.*—You sometimes see a joint, attacked with acute rheumatism of the most severe kind, completely relieved of it in twenty-four hours—the morbid action having been transferred to some distant part. From this it will pass, in like manner, to another, and another, until it shall have made a circuit of nearly all the large joints in the body. The lad Crutchley, who was in the top male ward a month ago, furnished a case in illustration: he additionally showed the tendency which rheumatic inflammation often has to attack symmetrical parts. He came in suffering from acute rheumatism, the affected joints being chiefly the shoulders and knees. After a time, the right shoulder was the solitary seat of pain, heat, and swelling; suddenly, this part became totally free from ailment, and was as well (the boy said) as it had ever been, but all its disorder was thrown into the corresponding shoulder; from this it disappeared most expeditiously, and then fastened upon the right knee; after having abided here for a time, it passed into the left knee; thence into the right wrist, and finally into the left one; its departure from this place was the last act of recovery.

This migratory disposition you never see in common inflammation: when this disappears, it is *in toto*, never repeating itself in remote spots, as a metastasis. Under this head may be mentioned the tendency of rheumatism to pass from superficial to deep structures. In this particular it is resembled by no other ailment except gout. The pericardium is chiefly liable to suffer from transferred rheumatic inflammation; an instance of it you saw in the case of Susannah Wilson, who occupied the top female ward about three months ago; more rarely the endocardium, and the muscular substance of the heart itself, are thus affected. The stomach and bowels are frequently seized in this wise, and the patient often experiences very severe pain. The boy Gill, in the middle male ward, you remember, suffered excruciatingly when the rheumatism lessened in his elbow and flew to his gastro-intestinal apparatus. Sometimes the brain suffers sympathetically, or metastatically, in acute rheumatism; and meningitis, or cerebritis, or coma

from congestion, occurs; sometimes the lungs, and congestion, serous effusion, pneumonia, or bronchitis, is the result; sometimes the kidneys, and then the patient complains of sudden pain in the loins, shooting down the thighs, sickness, difficult micturition, and diminished secretion of urine; rheumatism of the uterus, also, is a very troublesome and intractable ailment—so is that of the bladder, which frequently gives rise to symptoms like those of calculus, or prostatic disease, with which, indeed, it has been confounded. I am not aware that rheumatism of any internal organ ever occurs as a primary affection; I never saw an example of it; my opinion is, that it is always secondary of a seizure upon the joints or the muscles of locomotion.

3. *The Products of the Inflammatory Action.*—It has been said that rheumatism, however active, affecting the joints or superficial parts, never terminates in the effusion of lymph, in adhesion, in gangrene, or in abscess; but that its products are confined to an increase of the natural secretion of the joint, to a thickening of the ligamentous or cartilaginous structures, or to the deposition of earthy or saline materials upon them. The preparation which I show you, was formed upon the right parietal bone of a man who had for years suffered, almost periodically, from what seemed to be rheumatism of the integuments of the cranium. It is a hollow substance, as you see, about the size of a walnut, and consists merely of animal matter, carbonate and phosphate of lime, with a trace of lithate of soda.

In some rare cases, however, rheumatic inflammation resembles the phlegmonous in its products. You remember the boy Yardley, who died in the hospital about six months ago, of phthisis, and whose case I commented upon in my introductory lecture. When he came under my care, so latent was the disease that killed him, that he only complained of rheumatism of the right elbow-joint. He had often had it before, and on this occasion it was transferred to the elbow from the shoulder-joint. Several times the rheumatism flew to the stomach or bowels, leaving the elbow easy and capable of its accustomed motion. These, and other characteristics of the rheumatic action, left me in no doubt as to the nature of the local ailment in this boy's case; yet, as you know, pus formed in the neighbourhood of the joint, and was upon one occasion liberated by my able colleague, Professor Knowles. The patient was a very scrupulous

subject, and no doubt had for some time been labouring under tuberculous cachexia, which may in some measure account for the unusual products of the rheumatic inflammation; still, there are some people who would go so far as to say that, even in a case like this, rheumatism would not give rise to abscesses. As you well know, it did so, and I recal the case to your minds, to show you that the pathological law which I mentioned at the head of this paragraph is not obsolete.

Rheumatic inflammation affecting the internal organs runs pretty much the same course, and furnishes the same morbid products as inflammation in general. Thus, rheumatic pericarditis is commonly attended by serous or lymph effusion, and by adhesion; rheumatic carditis has had for its consequence an abscess in the substance of the heart; rheumatic pneumonia has been variously followed by red or grey hepatization, excessive sanguino-crous engorgement, or purulent infiltration; and rheumatic enteritis has been known to terminate in gangrene.

4. *The Acid State of the Secretions.*—This striking and invariable peculiarity in acute rheumatism I have repeatedly shown you in the cases we have treated in the hospital. In every instance you have seen that the saliva has been acid, often proportionately to the severity of the attack: in its normal condition you know, this secretion is alkaline, and you have seen it gradually return to a state of alkalinity as the patients have improved. The natural secretion of the skin is acid, but its intensity is greatly increased during acute rheumatism; in some cases, as I have more than once shown you, the acidity of the skin is strongest in those parts where the inflammation is highest. This localization of acidity is a singular circumstance: in rheumatism of one side of the face I have known the saliva secreted by the glands of that side to be acid, and that from the opposite side alkaline. The urine, again, has its acidity augmented in almost all cases of rheumatism. Even the blood, in whose serous portion free soda ought to exist, has been found strongly acid in severe cases of acute rheumatism. The lactic acid is that which is generally found under these circumstances; but the acetic is sometimes met with, and the uric and its salts, in most cases, abound in the renal secretion.

This acidification, so to speak, of the system in general, or of certain parts affected with rheumatism, is not only a leading pathological feature in this disease, but is, perhaps, the one which gives it its specific character, or constitutes what may be called the rheumatic diathesis. In particular, it resembles it to gout, and suggests the probability of the functions of digestion and assimilation being in some way concerned in producing or perpetuating the morbid phenomena: if this latter be true, again, it will tend towards the explanation of the hereditary character both of gout and rheumatism.

There are other pathological items in the allment I am speaking of upon which I would fain dwell, but that the direct duties of this chair give no latitude to speculation. To regard acute rheumatism, then, in that practical light which relates directly to treatment, there are two leading points for consideration and guidance: these are, *inflammatory action* and *acidification*. These are the two morbid conditions which specially need correction. To say that either needs more than the other would be to make an assumption beyond what our present knowledge would justify, and might open a precedent for exclusive and, consequently, for bad practice. For it sometimes happens that the inflammatory symptoms run excessively high, and demand immediate measures, not moderate in their energy, to save the patient from sacrifice. This is especially the case in metastasis to any vital organ. Under these circumstances, as to regarding the acid state of the system and its secretion to the exclusion of those more prominent peculiarities of excessive inflammatory action, would be the height of bad judgment and generalship. I am of opinion, that it, early in the acco-

sion of the disease, the acid state and tendency were corrected, in a great majority of cases there would be little inflammation to call for active management. I do not mean to say that these two pathological conditions relate to each other as cause and effect; but this I do know, that the acidity is greatest where the inflammation is highest; that an increase of acidification is often a precursor of an increase of febrile and inflammatory action; and that the correction of the former is often followed by a complete cessation of the latter. I speak with confidence, gentlemen, upon this subject, because my opinion is the result of careful observation and not very limited experience. Twelve years ago, and for five years previously, I was in the habit of treating rheumatism, and seeing it treated, with a sole regard to one of its pathological features—*inflammation*. I have seen blood taken by ounces, and by pounds, and the patients left the weaker and the worse for the loss of it; I have seen them sink under depletive treatment, and yet their pains continue unabated, until approaching dissolution rendered them unconscious of agony; I have seen the most profuse purging from colicium, and alarming depression from digitalis, yet the fever and local inflammation rise again, the more vigorous for the loss of power to resist them; I have seen mercury given in all doses, and to every extent short of actual sloughing of the mouth, and yet the rheumatism no better for the impregnation of the system; narcotics of all kinds I have seen tried, and, though often of service, they have sometimes rendered that service tardily, and again not at all. Mark, I am not wishing to underrate these remedies; they are excellent in their way, and when administered with judgment, in cases that absolutely require them, are often productive of much benefit. What I want to show you is, that, in the majority of cases of acute rheumatism, they can be dispensed with; and that, when actually called for, they need not be pushed to the extent that was the fashion some years ago. To take pounds of blood away from a man, to mercurialize him severely, or to produce excessive prostration by digitalis or colicium, is to try a very serious experiment upon his future health and strength. Many a man has been invalidated for life, been rendered anasarctous, irretrievably dyspeptic or palsied, by these fierce onslaughts upon his circulating and nervous systems. The maximum beauty of medical practice is simplicity; its success is greatest when, in doing the most good, it does the least harm in consequence.

In advocating the alkaline treatment of acute rheumatism, I am speaking of no novelty of practice. For years past it has been recommended, but by whom first I do not know. At the same time I think it right to state that I believe there are few, if any, practitioners who have given it a fairer trial, have trusted more exclusively to it, or have derived better results from it than myself. For six years past I have tried it in every case of rheumatism that has occurred in my dispensary and private practice, and seldom have I been obliged to have recourse to other remedies. I have never, in this space of time, had a case that has terminated fatally, and yet in not one instance have I ordered bleeding from the arm. Leeching and cupping, and these but rarely, have been the extent of my depletive measures. Yet I have had many cases which have equalled, if not exceeded, in severity those which I have seen progress indifferently, or not at all, under the opposite mode of treatment. Yet do not mistake me, and suppose that I am lauding alkalis as specifics in rheumatism. Nothing is further from my intention than to do so: my experience inclines me to the belief, as I have before said, that there is no such thing as specificism in medicine. An agent of this class, you know, should in all cases be infallible: I never met with such a curiosity. All I wish to say and to prove, from my own observation, is, that in the majority of rheumatic cases, alkalis will alone prove curative; and that, when they fail of doing thus much, they will at least supersede the necessity of large doses of more uncertain and more potent remedies.

I could give you many cases from my dispensary note-book, but I prefer confining myself to those which you have yourselves seen in the hospital.

The first case to which I will call your attention is that of Frances Child, a married woman, aged twenty-six, who was admitted under my care on the 17th of December last. She was the subject of acute rheumatism, in an exceedingly severe form, of about ten days' duration. Most of her joints, but especially her knees, elbows, ankles, and wrists, were largely swollen, very hot and red and painful. She could scarcely move hand or foot, and when we made only slight pressure over the affected parts, the poor sufferer screamed in agony. She was perspiring moderately, but her skin had so strong an acid odour that you remember we distinctly recognised it at above a couple of yards' distance. As I leaned over her to auscultate the heart, this acid stench was so intolerable that I could scarcely endure it long enough to enable me to effect my purpose. The reaction of the perspiration, as also that of the saliva, was instantaneous, and most energetic, upon the deepest coloured litmus-paper. The patient also complained of a distressingly sour taste in her mouth. There was some pain in both the sides, slightly increased on full inspiration, but especially aggravated by moderate pressure made over the intercostal spaces; the sounds of the heart were not unnatural, and I therefore concluded that this pain originated in rheumatism of the intercostal muscles. The face was flushed and hot; hands burning; respiration accelerated; pulse 146, firm and bounding; tongue coated with a thick pale fur in the centre, and red at the edges and tip; thirst urgent; no appetite; urine scanty and very high-coloured; bowels moderately open. She was ordered toast-water for drink; to have a hot bath containing two ounces of carbonate of soda, at bedtime; and to take the following:—

R. Sodæ bicarb., ʒij.; mist. camphoræ, ʒviii.; M. ft. mist. cujus cap. coch. larg. duo tertius horis.

The next day she was slightly better. She fell asleep shortly after having been carried from her bed, and slept for about three hours, which she had not done for more than a week previously. Her perspiration and saliva were less sour, and there was less tension, heat, and tenderness of the joints. She was simply ordered to continue her mixture.

The day following she was improved in all respects, except that her bowels had not been moved for twenty-four hours. She had a little bilious tinge in her face: she was ordered a powder, consisting of three grains of calomel and four of scammony, to be taken directly: her mixture to be continued.

The next morning she was sitting up in bed; and you remember the smile of thankfulness which played over her face when she told us how much better she felt. Her powder had operated twice; she had slept through the greater part of the night, and was now the subject rather of weakness than pain. Still, there was a little tumefaction and tension of her joints, and her saliva was slightly acid; so she was ordered to continue her mixture three times a day.

On the 28th, eleven days after her admission, there was not a trace of rheumatism left, and she was requested to discontinue her medicine. From this date to the 20th of January she never took another dose of physic; but I thought it advisable to let her remain in the hospital thus long, both that she might recover strength, and that we might see if there were any relapse. There was nothing of the kind—she steadily improved to the end, and left the hospital quite well.

Now, considering the severity and duration of this case, a single aperient through the whole time of its treatment was little enough; yet that was all that was taken. The hot bath did considerable good, but that I attribute chiefly to the alkali in it, for the woman had tried simple hot baths before, but without any benefit; and I have

often made comparative trials of these, and those containing an alkali, and without exception invariably in favour of the latter. The camphor mixture I attach no importance to whatever, for I never find any difference between making this and plain water the vehicle of the soda: when I give the former, it is simply with a view to mask the taste of the soda, which to sick people is very unpleasant. We have nothing left, then, but the alkali to which to impute the chief curative good in this case; and I think you will agree with me, that I am not in error in giving it the credit of the main service.

On the same day that this patient came in, another was admitted, labouring also under rheumatic fever. This was Susannah Wilson, who occupied the top female ward. Her symptoms were so precisely similar to those of the preceding case that it is not necessary for me to detail them in full: they had existed four days. Her rheumatic pains, which were very severe, occupied chiefly the shoulders, hips, elbows, and knees: the concomitant fever was also very strong. The point in which she differed from Child was in the state of her pulse: its beats were 130 per minute, but it was feeble; there was nothing unnatural, however, in the sounds of the heart. She was ordered a hot bath, containing an ounce of carbonate of soda, at bedtime, and the same soda mixture which was prescribed in the previous case.

On the following day we learned that she had passed a comfortable night, having felt much better for some time after leaving the bath. The saliva and perspiration were decidedly less acid, but the pains were still very severe. Her bowels not having acted since her admission, she was ordered five grains of compound colocynth pill directly, and to be repeated every three hours until full cathartic action should be produced. The mixture to be continued.

The first pill operated, and the patient was the better for it. On the next day, however, her pains were still very severe, and her pulse quicker; I had every confidence in the alkali, but fearing lest I might be repaying an unworthy reliance upon it, and be unduly biased in its favour, I added to the mixture a drachm of tincture of colchicum. I had no experimental conceit to gratify, but rather to do the best I could for my patient. I ordered her, additionally, an opiate draught at bedtime. This caused her to sleep, and the next morning she was a shade better. The new mixture was continued through this day, but she was so purged and prostrated by the colchicum, and her pains at the same time were so violent, that I determined to fall back upon the original. Accordingly, she was ordered the soda mixture as at first, and a soda bath at bedtime.

The day following she was slightly better, and I resolved then to trust to the alkali singly. She did not bathe again, but took her mixture in double doses, and within a week was quite free from ache or pain. She then discontinued her medicine; but several days afterwards she was unfortunately caught in a heavy rain, took cold, and had severe rheumatism in both elbows. There was no concomitant fever in this instance, so I merely ordered her elbows to be thrice daily fomented with hot soda and water, and in a few days she was quite well again. She thus continued for near a month without any medicine, or any return of ailment, when she left the hospital well.

Shortly after the dismissal of this patient, we had another, Mary Hill, in the middle female ward. She had severe rheumatism, of recent occurrence, affecting both elbows and wrists. The constitutional symptoms were not urgent. An alkaline fomentation to the affected parts relieved them of their suffering within a week. She then went home to bury her father, caught cold, and came back again with acute rheumatism, confined to the knees, legs, and ankles. She could not even support her own weight. Local alkaline baths were again used, without any other remedial means, and in about ten days she was dismissed cured.

George Dawson, you remember, came into the top male ward on April 30. He had severe rheumatism, extending from the right shoulder to the tips of the fingers on the same side. His hand, as you saw, was enormously swollen. I learned from his surgeon, under whose care he had frequently been, that leeching, phlebotomy, colchicum, and mercury did him no good. All he had in the hospital was the soda mixture I have already prescribed; alkaline fomentations three or four times a day to his arm and shoulder; and a cathartic pill when necessary. By the 5th of May he had no further need of medicines, but I allowed him to remain in the hospital to recover his strength, and on the 12th he left from his own desire to go back to his employ.

Crutchley furnishes you with another case. His rheumatic seizure was very severe, but he took nothing but carbonate of soda, and had an occasional alkaline fomentation, and he got well. He had two relapses from exposure, and was again treated on the alkaline plan, and with the same results.

There are several more cases you have seen in the hospital, which I could recapitulate, did time permit: but you must all remember them, for I have made clinical observations upon them day by day, and it is not necessary for me here to dwell further.

I ought to add, however, that my reason for preferring soda in these cases is, because I regard it as the natural alkali of the animal system. It is the free alkali of the saliva, the blood, the bile, and the semen. I only use potash when there is abundant lithic deposit in the urine; and this, because the lithate of potash is less soluble than that of soda.

In conclusion, whilst I commend to your favourable notice this mode of treating acute rheumatism, do not receive it from me as an unexceptionable plan. If you will steadily pursue it, I am certain that the majority of cases will yield to it; but, should you meet with any that do not, attach no absolute faith to it, but use any other measures which immediate circumstances may call for. Look to the secretions, especially those of the skin, liver, and kidneys: if any general remedy or remedies will correct these, trust thereto; if not, try more direct ones, but avoid extremes!

A COURSE

OF

LECTURES ON SURGERY,

BY

SAMUEL COOPER, Esq., F.R.S.,

Professor of Surgery to University College, London;
Consulting Surgeon to London University Hospital, &c.

LECTURE VIII.

Another powerful remedial agent in inflammatory diseases is tartar emetic, either in large or small doses. Its beneficial effects are produced, when employed in small doses, by increasing perspiration; when used in larger doses, by exciting nausea, and thereby promoting perspiration, and reducing the pulse at the same time. There can be no rational doubt that great benefit is derived from the use of tartar emetic for either of the purposes I have just noticed, as well as the slight purgative property it possesses; but we must not place entire dependence on this medicine to the exclusion of blood-letting; and, indeed, I am of opinion that the treatment of inflammation would not be less severe, and perhaps not so effectual, as if the lancet were employed. Rasori introduced the practice of administering large doses of tartar emetic in certain forms of inflammation into Italy many years since, carrying the dose to two grains, or even more; and this mode of treatment has been employed in England to a considerable extent in pneumonia, with a fair amount of success. Should you determine to employ this remedy

after the manner of Rasori, you must begin with smaller doses—say a quarter of a grain, repeated at short intervals, and gradually increase the dose. You will find that the first few doses generally produce vomiting, but afterwards what is called tolerance is established, and the tartar emetic ceases to produce its ordinary emetic effect—even when the dose is doubled or tripled. When tartar emetic is administered purely for its diaphoretic effect, the dose may be about one-sixth of a grain every four or six hours; when as a nauseant, a quarter of a grain may be given every two or three hours.

It is occasionally necessary, on account of the extreme pain which sometimes accompanies inflammation, to give opium, although this remedy is generally to be avoided if possible. We do not always succeed in alleviating pain, and frequently increase the fever, restlessness, and constipation, by its use. Opium is often given after severe operations, to alleviate pain and quiet the nervous system; and here it succeeds much better than when inflammation is already established. It is preferable to use certain preparations of opium, as acetate of morphia and liquor opii sedativus, to the drug itself, as these preparations are supposed to possess less of the stimulating and irritating principles of opium.

Low diet must be enjoined in all cases of inflammation, and the patient prohibited from taking animal food, wine, and other fermented liquors. The patient should be kept moderately cool, but not so cold as to produce chilliness and check the cutaneous transpiration. He should be placed in a large well-ventilated chamber, and no conversation or noise be permitted. You will find that ignorant nurses are very fond of keeping the patient warm, by heaping blankets and other coverings over him; but this you must not permit. Gentlemen, the means I have pointed out to you constitute the general treatment of inflammation, and form what is commonly called the antiphlogistic treatment; from which I must now turn to the local means employed for the purpose of removing inflammation.

One of the local effects of acute inflammation is an increased temperature of the part, which is distressing to the patient, and the surgeon would probably feel inclined to adopt means to diminish this painful sensation of heat, if only with the object of relieving the patient from the uncomfortable state in which he is placed by it; but he has other and more important reasons for so doing. It is well known that heat promotes all the processes going on in the system, and inflammation among the rest; and, therefore, by diminishing the temperature of the inflamed part, we are at the same time diminishing the inflammatory action. The most common means employed for this purpose is the application of linen dipped in cold water, or a cold evaporating lotion. A most useful lotion is made by adding a drachm of liquor plumbi, diacetatis, and two ounces of camphorated spirit, to a pint of cold water; or equal parts of cold water and liquor ammoniac acetatis, with some camphorated spirit, may be substituted. In all cases where the surface of the skin is broken or lacerated the simplest form of lotion is to be preferred. The most important thing is to keep up a continued evaporation, which you know produces cold. For this purpose we must order the linen to be kept constantly moist, and not allowed to dry, as it then becomes hard and stiff, and increases the pain and uneasiness by producing pressure and irritation.

It is a curious circumstance that in many cases the application of cold produces rather an injurious than a beneficial effect, and warm applications are indicated. We are unable to give a satisfactory explanation of this fact. Cold is useful in diminishing the heat of the part, as we have already seen; but, as regards warm applications, the explanation generally given is, that they soften the inflamed textures, and thereby relieve tension. Warmth combined with moisture is in some cases more efficacious than cold; a warm poultice being frequently more useful than a cold lotion. It is, however, chiefly in

These forms of inflammation which have a strong tendency to supuration that warm and emollient applications are most beneficial. In the critical abscesses of fevers, boils, carbuncles, whitlows, and collections of matter at or about the anus, poultices and fomentations are most valuable. The common linseed-meal poultice is one of the best of these. To prepare it you pour some hot water into a basin, and gradually shake the linseed-meal into it, keeping the whole well stirred with a spoon until it becomes of a proper consistence. It may then be spread on linen or

Many persons spread a little oil on the face of the poultice to prevent it from adhering to the part; but this is unnecessary, as the oil is of an oily nature. Other poultices are made with bread and water, bread and milk, or bread and Goulard lotion. These are in such constant use that it appears scarcely necessary to mention their preparation.

With regard to fomentations—you may make a very good one by boiling a quarter of a pound of chamomile flowers or poppyheads in a gallon of water. The liquid when strained is fit for use. It is unnecessary for me to examine the efficiency of these herbs, or to ascertain whether the good effects of the fomentations are to be attributed to them, or to the heat and moisture they impart. But I should recommend you to employ them because patients are apt to fancy that simple things are not efficacious. When the inflammation has declined under the use of the remedies I have described, the parts often remain weak and deficient in tone, especially when the inflammation has attacked the eyes or joints. In these cases it is proper to employ means for improving the tone and restoring the functions of the part. After inflammation of the joints, blisters are exceedingly efficacious in promoting the absorption of effused lymph, and diminishing the thickening of the textures. Blisters are not to be applied in the early stages of the inflammation before other depleting measures, but no applications are better for removing the stiffness and thickening which remain after acute inflammation.

In cases of inflammation some examples will be found in which it is doubtful whether it is better to use cold or warm applications, in such cases we must take the sensations of the patient as the indication for it is certain that the kind of application which is most agreeable to the patient is that which will prove most beneficial.

Counter-irritation is a powerful means of lessening inflammation. It is useful in several ways, one of which is by producing inflammation of the skin, either near to, or more distant from the part affected, but in some situation which will sympathize with it. Here we excite inflammation in a less important part to remove inflammation of one of greater importance, so that, as the one increases, the other and most dangerous declines. The old terms, derivation and revulsion, apply to forms of counter-irritation whereby the blood or fluids are drawn from one part to another, either in the immediate vicinity or at a distance from the first, and the efficacy of counter-irritation, perhaps, chiefly depends on this kind of derivation. It is not always desirable to excite counter-irritation very near the part affected, especially in acute inflammation, because, if the inflammations are very near to each other, they may join and aggravate the original affection. In ophthalmia, for example, blisters are more frequently applied to the nape of the neck than the temples, because in the latter case the eyelids might become inflamed, and the inflammation of the eye itself increased, instead of being diminished. You must, therefore, follow the general rule of not applying blisters too near to inflamed parts, for the reasons I have mentioned. Blisters, however, are not the only principle that produce a copious discharge of serum from the skin, from which, if good is derived, and, if the cuticle be afterwards removed, a purulent discharge is set on foot which may be continued for a length of time, dressing the blistered surface with savin or other irritating ointment.

I must again warn you, gentlemen, against

employing counter-irritation in acute inflammation before you have sufficiently depleted the patient by the general antiphlogistic measures. I have advised, because it is often useless, or even injurious, under such circumstances, by increasing fever and restlessness, and thereby augmenting the inflammation. Counter-irritation, when not preceded by bleeding and purging, will not produce the beneficial effects anticipated from it.

There are several other forms of counter-irritation, such as setons, issues, and the tartar emetic ointment, which are all applicable in different cases. It is chiefly in chronic forms of inflammation, whether originally so or following acute inflammation, that these are employed. The tartar emetic ointment is made by carefully mixing a drachm of tartar emetic with an ounce of common lard or spermaceti ointment. This ointment, when rubbed on the skin, has the effect of producing pustules very much resembling those of smallpox, which may be kept up for any length of time by occasionally repeating the application of the ointment. In the chronic forms of inflammation, whether originally chronic or supervening on acute inflammation, these counter-irritants and derivatives, antimonial ointments, blisters, issues, and setons, are of the greatest importance as curative agents. The external application of nitrate of silver in some forms of inflammation is attended with far more beneficial effects than we might have anticipated from reasoning, and for which we cannot assign any very satisfactory explanation. Mr. H. is a brilliant student, the great merit of introducing a new method in this practice, which has undergone the test of experience in a most satisfactory and judicious manner. In that form of phlegmonous inflammation which occurs in the fingers, on the roots of the nails, and ends in the formation of an abscess, called in this situation paronychia or whitlow, the early application of nitrate of silver will frequently prevent the formation of pus, which could scarcely be effected by any other mode of treatment. When nitrate of silver is so applied simply to blacken the epidermis, it is more often successful in dispersing inflammation than you would be led to expect. I have seen the application succeed in many instances, and, although I do not understand the principle on which it operates, I have no hesitation in bearing testimony to its efficacy. Under such circumstances the theory of the action of any remedy is of secondary importance. I may mention that I have seen the external application of nitrate of silver successful in dispersing serofulous enlargements of the glands of the neck. It cannot be expected that any remedial agent should always be successful in preventing suppuration or other mischief, but this application has been successful in so large a number of instances as to justify trial. In some instances it is only necessary to apply it in such a manner as to blacken the cuticle, but in others it is advantageous to produce vesication. Mr. Higginbottom applies the nitrate of silver in the following manner. He first perfectly cleans the skin by washing with soap and water, and, after moistening it with cold water, passes a stick of nitrate of silver over it at two or three times when the intention is simply to blacken the skin, but more frequently when vesication is to be produced. Take all other remedies, this may have been too much praised, but I have seen it so frequently attended with beneficial results that I should be wrong in not recommending it to you.

Counter-irritation is of great utility when chronic inflammation has attacked a mucous membrane. In many of these cases cold and astringent lotions may also be employed. In chronic inflammation of the conjunctiva, astringent lotions are among the most common modes of treatment. By the use of astringents the dilated vessels recover their natural tone and calibre, and a stop is put to the increased action of these vessels which causes them to secrete pus instead of mucus.

A common consequence of acute and chronic

inflammation is the effusion of lymph and other fluids, the absorption of which must be encouraged in order to restore the part to its natural state. Such effusions or deposits are sometimes so copious as to impede or even altogether obstruct the action of the organs, and to cause a sensation of weakness, which is very troublesome to the patient. Blisters are perhaps the most powerful agents in exciting absorption of such matters; but we may often employ stimulating embrocations, mercurial or iodine ointment, for the same purpose with great advantage. When we require the long-continued action of a blister, we may do this either by a repetition of the blister after the first has healed, or keep it open by savin ointment. Blisters purgatives are also useful in exciting the action of the absorbents. The internal use of iodine or mercury is well adapted for the removal of particular kinds of inflammation. Lotions containing the murate of acetate of ammonia, with vinegar or camphorated spirit, possess similar discutient properties.

Cold applications do not possess the same power of diminishing or removing chronic inflammation as we observe them to have in moderating the acute forms of this disease, although it is a general opinion that even chronic inflammation may be much retarded by these remedies. They are by no means so effective as the various forms of counter-irritation I have already discussed.

Hitherto, gentlemen, I have spoken of the treatment of ordinary inflammation, but you will soon discover that specific inflammation demands particular remedies in addition to those usually required for the removal of common inflammation. Thus specific inflammation of gout and rheumatism is most rapidly removed by colchicum, serofulous inflammation, by the external application and internal administration of iodine, or other alteratives, which are capable of correcting the perverted action of the system; and in a neural inflammation it is usually right to employ mercury with greater freedom.

It only remains for me to notice the treatment of fever, which accompanies acute inflammation. Although I have not much to say on it, because the treatment employed for the removal of the inflammation is equally efficacious in the removal of the fever. The inflammatory fever rises with the inflammation itself, increases with it, and declines as it declines, so that in curing the one you cure the other. John Hunt has called this fever the universal sympathy of the system with the disturbed state of a part. The symptoms of inflammatory fever vary with the nature, extent, and violence of the inflammation, the constitution of the patient, and the functions of the part or organ. You have increased action of the heart and arteries, the pulse is full and strong when the inflammation is not seated in the vital organs, the secretions are more or less suppressed and disordered, the skin is dry and harsh, the mouth dry, with great thirst, and the tongue coated with a white fur. Inflammatory fever exercises a great influence on the secretion of ulcers and wounds; for we find that, while the fever is violent, the prevalent secretion is scanty and of an unhealthy character. The urine is much diminished in quantity, high-coloured, and clear, and does not deposit the latent sediment until the fever is on the decline. The heat of the surface is much increased, and the nervous system is disturbed; restlessness, headache, vigilance, and delirium being the indications of this disturbance. The bowels are constipated from suppression of the ordinary secretion of those organs. In very bad cases other nervous symptoms occur—twitches or convulsive movements of the tendons, called subsultus tendinum, which is a very bad symptom. The appetite is altogether lost, and the stomach often disturbed by nausea and vomiting. The ordinary treatment of inflammation will in general suffice for the subdual of the inflammatory fever, but, where severe headache or delirium exists, the application of leeches to the temples and cold lotions to the head will prove

rus. When the stomach is much dis-
turbed, evacuating draughts, containing a
drop of laudanum or tincture of hyoscin-
us, may be given, and fomentations applied to
the epigastrium. Other occasional symptoms are
to be combated by medicines calculated to re-
lieve them. I need not add anything more to what
I have already said when placing before you the
treatment of inflammation.

DUMAS ON ORGANIC CHEMISTRY No. XXII.

(Continued from page 271.)

(CHYLE AND LYMPH)

We have seen that the venous absorbent, which is so active on the surface of the stomach, carries directly into the blood the major part of the azotized aliments which are rendered soluble by the action of the gastric juice. The products of the intestinal digestion pass into the blood in a less direct manner: they traverse in especial apparatus, whence they are led into the general circulation. This apparatus consists of the chyliferous vessels which carry away the principles which the intestinal digestion has rendered fit to be absorbed. We can readily understand that it is impossible to collect, in a state of purity, the liquid which the radicles of the chyliferous suck up from the intestine, and which has been designated by the name of chyle for the chyliferous, properly so called, vessels of the intestine; and, moreover, they immediately mix themselves with the lymphatic vessels, so that the chyle, which we may obtain from the trunk of a chyliferous vessel or in the thoracic duct, is already mixed with a quantity of lymph which it is almost impossible to appreciate. The properties which have been attributed to the liquid chyle belong, in fact, to a mixture of chyle and lymph, such as that which we meet with in the thoracic duct.

Generally speaking, the chyle is a white milky liquid, sometimes of a rose colour, or even red. It contains fibrine and albumen, consequently it undergoes a spontaneous coagulation after the lapse of eight or ten minutes. The serum which surrounds the fibrine clot may be coagulated by heat. It is probable that it is the lymph which conveys into the chyle the fibrine which is found there. I have, in fact, remarked that this liquid coagulates spontaneously only when collected below the lymphatic anastomosis of the mesentery. The radicles of the chyliferous vessels absorb the fatty matters: the chyle is, therefore, very rich in fatty globules with which we find mixed some colourless lymph globules. Sometimes the chyle is of a rose colour, or even assumes a clear red tint, yet it never holds blood globules, properly so called. It also those salts which exist in the blood.

The following are some analyses of the chyle which are due to MM. Tiedemann, Gmelin, and Simon. The fluid examined was expressed from the thoracic duct of a horse.

	Tiedemann and Gmelin			
	I	II	III	IV
Water	924.1	81.8	918.03	879
Coagulum	17.5	4.3	7.08	1.9
Albumen	45.1	34.3	42.08	19.1
Fatty matters	as trace	small quantity	16.17	quar-
Water extract	7.9	0.2	11.62	7.2
Alcohol extract and salts	8.8	2.3	2.00	0.9

	Simon		
	I	II	III
Water	940.6	924.0	916
Fibrine	0.3	0.8	0
Fatty matter	1.2	10.0	0
Albumen	12.7	16.1	61
Colouring of the blood	0.1	trace	5
Extractive matters and salts	10.1	13.7	12.2

These analyses suffice to show the great variation which the composition of the chyle may present. We should especially remark the difference in the proportion of the fatty matter which it contains, but there is nothing surprising in these variations, for the composition of the chyle must

necessarily change according to the nature of the ingested aliments. MM. Tiedemann, Gmelin, Bouchardat, and Sandras have performed some interesting experiments on this subject.

The chyle of mammals, which have been fed on substances combined with a large proportion of oil of sweet almonds becomes opaque, and we may, by means of ether, extract from it as much as ten to fourteen per cent. of almond oil. We discover, in the same manner, suet which may have been mixed with the aliments. Should we tint these matters with alkanet or turmeric, we still find the chyle colourless, the chyliferous vessels refusing to absorb the colouring particles. Wax passes into the chyle in but small quantity; if, however, we dissolve it in olive oil, in the proportion of four parts of oil to one of wax, we shall meet with it in very considerable amount. As MM. Bouchardat and Sandras have remarked, these experiments plainly show that the chyle absorbs from the intestine merely the fatty matters which are found in a state of minute division, but otherwise unaltered in the chyle.

Some experiments have been made on the human lymph, and also on that of the horse. We may conceive that it is an easier matter to collect this liquid in a state of purity than to procure pure chyle. Its properties, however, appear to be identical with those of the latter liquid. According to MM. Tiedemann and Gmelin, it contains—

Water	96.0
Fibrine	1.0
Albumen	2.0
Chloride of sodium, carbonate and phosphate of soda, and in small matter	5
Extractive matter and lactate of soda	9

We should remark that fat has not been pointed out among the materials of the lymph.

MM. Muchend and Colberg analysed some lymph which exuded from a wound on the dorsum of the foot. It contained—	
Water	96.0
Fibrine	5.2
Albumen	4.4
Extractive matter	3.2
Fatty matter	2.6

Chlorides, alkaline carbonates and lactates, sulphate and phosphate of lime, and traces of oxide of iron.

Intestinal Matters. The excrements are composed of the residue of the aliments and all those products of the secretions which are unfit for undergoing any renewed absorption. We designate by the name of meconium the matters which accumulate in the intestinal tube of the fetus, and which consist merely of the refuse of the secretions. We have but one analysis of human meconium, and for this we are indebted to M. I. Simon. According to his description which he has given it is a soft mass of a blackish brown colour, having a sickly odour with a sweetish taste. When examined by the microscope, we discover in it, besides numerous particles of epithelium, masses of small lamellae resembling crystallized cholesterol, as well as flat globules which may be compared to de-colourized blood globules. Ether removes from it the fatty matters and the cholesterol, while dilute alcohol extracts from it a matter possessing the properties of casein. One hundred parts of dried meconium, according to M. Simon contain—

Cholesteroline	100.0
Extractive matters mixed with bile	
Casein	
Biliary matter	
Mucus, albumen, &c.	

The ashes of meconium were analyzed by M. Payen, who found in them some alkaline carbonates and phosphate of lime.

Let us now place by the side of this first analysis one made upon the fecal matters of an infant six days old, which had been suckled by its mother. This matter was of a pappy consistence, it was yellow, and possessed the odour and taste

of scales of epithelium, but a considerable quantity of globules of fatty matter derived from cholesteroline.

A hundred parts of the dried residue contained—

Fatty matters	68
Colouring matter of the bile and fat	18.4
Albumen or coagulated casein	18
Loss and water	14

M. Berzelius examined the excrements of a man who had been fed on brown bread and meat. They consisted of adherent masses which mixed but slowly with water, and which formed with it a thick pappy mass, difficult of filtration even through linen, a brownish, muddy liquid eventually passed through, which, after a few days, became sufficiently clear for it to filter through paper.

The clear liquid was rapidly coloured by contact with the air. Abandoned to spontaneous evaporation, it became gradually covered with crystals of the ammonio-magnesian phosphate, the formation of which was owing to the ammonia produced by the decomposition of the azotized matters, and to the phosphate of magnesium dissolved in the excrements.

The soluble portion of the excrements, when evaporated to a syrupy consistence, was diluted with alcohol, and the alcoholic solution mixed with a little distilled water. The residue was treated by sulphuric acid, which precipitated from it a brown, coherent matter, in chief part composed of the materials of the bile, and which resembled cholelithic acid. The matter, insoluble in alcohol, was almost entirely composed of albumen.

Alcohol returns the brown extractive matters of an animal nature and some alkaline lactates.

The insoluble matter which is deposited from the thick liquid previously filtered through linen, and which so readily blocks up the pores of the paper, appears to be almost entirely composed of mucus. It is dissolved by potash, ether and alcohol remove from it some fatty matters and biliary resin (cholelithic acid). The mass, after being acted on by boiling alcohol, yields to water a yellow matter which rapidly putrefies, at the same time that it assumes a very deep colour, and gives out an odour characteristic of putrefied urine.

We may, in like manner, isolate this principle by treating the matter of which we have been speaking, by hydrate of lime, which forms an insoluble combination with the fat, and also with the biliary resin. The remaining substance is soluble in lime water, and may be isolated by precipitating the lime by a stream of carbonic acid, or by the addition of oxalic acid.

The matters left on the cloth are principally composed of the intact debris of the aliments—such as the bran or skin of potatoes, and other vegetable matters. Their composition varies according to the nature of the ingested aliments.

M. Berzelius concludes, from his analyses, and from the reactions which he has observed, that the fecal matters contain an insoluble combination of biliary matter with the secretions of the intestinal tube, a combination which is destroyed by alcohol and by lime. Annexed are the result of his analyses—

Water	76.3
Matters soluble in water	
Bile	0.9
Albumen	0.9
Extractive matter	2.7
Salts	1.2
Insoluble matter of the aliments	7.0
Insoluble matters of the intestinal canal—mucus, biliary resin, animal matter, &c.	12.6

To determine the nature of the salts contained in the fecal matters, M. Berzelius acted on three ounces of fresh excrements by a large quantity of water. The aqueous solution, when evaporated to dryness, left a residue which gave, on

Carbonate of soda (arising from the isotate)	3.5
Chloride of sodium	4.0
Sulphate of soda	2.0
Phosphate of magnesia	2.0
Phosphate of lime	4.0

15.5 grs.
The dry excrements leave, on incineration, 0.15 per cent. of nearly black ashes, which contain—

Phosphate of lime and magnesia, traces of sulphate of lime	0.100
Carbonate of soda	0.008
Sulphate of soda, with traces of sulphate of potash and phosphate of soda	0.008
Silica	0.016
Carbon	0.018

0.150
The excrements, when distilled with a certain quantity of water, furnish a very fetid liquid containing sulphuretted hydrogen; a brownish grey precipitate is formed by the acetate of lead, at the same time that a repulsive odour is given out. Chlorine whitens the human excrements. When treated by sulphuric or hydrochloric acids, they disengage a very strong odour and acquire a violet or black colour.

MM. Kinhof and Thaer made some experiments on the excrements of the cow. M. Morin also published a very complete analysis of this substance; the results are as follow—

Water	70.00
Vegetable debris	24.08
Green resin and fatty acids	1.52
Unaltered matters of the bile	0.60
Bubulins	1.60
Albumen	0.40
Resin of the bile	1.60

100.00

The body, which M. Morin calls bubuline, resembles in all its properties the yellow extractive matter which Berzélius discovered in the human faeces, and which acquires a brown colour on contact with the air.

Intestinal Concretions.—Biliary concretions are somewhat rare in animals; the bovine race has however, presented some examples of them. Bzoars or stones are often found in the intestinal canal; these have sometimes nuclei formed by an agglomeration of hairs which the animals swallow in the act of licking themselves. They ordinarily possess a greenish brown colour; they are soluble in the alkalis; the acids precipitate the latter solutions; water dissolves them but very sparingly, at the same time assuming a yellow colour. Some of them are soluble in alcohol, whilst others are altogether insoluble in that menstruum.

The large calculi, known under the name of *oriental bezoars*, appear to be biliary concretions at least the substance which forms the greater part of these stones is also met with in those usually contained in the gall-bladder. It is an acid body, which was discovered by M. Goebel, and which has been more particularly studied by MM. Woehler, Etting, Will, Malaguti, and Sarzeau. It has been designated by the name of *lithofellic acid*.

Lithofellic acid, which constitutes a great number of calculous salts, is crystallizable. To obtain it in a state of purity, we have merely to dissolve in alcohol the calculi which are formed of it, to decolorize the solution by animal charcoal, and then to evaporate it. It presents itself under the form of small brilliant hexagonal prisms, which are hard and readily pulverizable. These crystals are insoluble in water, and very slightly in ether. They melt at 205° C., and form a crystalline mass on cooling; if heated to a more elevated temperature, they form a vitreous mass, which melts at 165°, and which constitutes a true isomerization. If redissolved in alcohol and allowed to cool, we obtain anew crystals of pur fellic acid.

This acid is soluble in acids. It combines with salts; the ammoniacal destroyed by spontaneous and baryta it forms salts which are insoluble in water. The salt of silver, in like manner, is but slightly soluble; it is obtained by precipitating a solution of lithofellic acid of ammonia dissolved in alcohol by nitrate of silver; the precipitate is to be redissolved by heat, and once more crystallized by cooling.

Lithofellic acid, according to MM. Etting and Will, is represented by the formula: $C^{10}H^{12}O^8$.

According to Woehler, its constitution is $C^{10}H^{12}O^7$, $H^{12}O^8$.

Treated by nitric acid, it gives birth to a new body—*lithazofellic acid*—containing, according to MM. Malaguti and Sarzeau, two equivalents of nitrous vapour, Az^4O^8 , and six equivalents of oxygen, which together replace eight equivalents of hydrogen. It is consequently derived by substitution from lithofellic acid, as we see by the following formulae:—

By dry distillation, lithofellic acid is resolved into water and into *pyrolithofellic acid*, in accordance with the following equation:— $C^{10}H^{12}O^8 = 2H^2O + C^{10}H^8O^8$.

Very recently, M. Woehler extracted from a bezoar an acid different to lithofellic acid, and which he had at first viewed as a peculiar body. It has, however, been recently proved that this *bezoardic acid* is identical with the *ellagic acid* discovered long since by M. Braconnot. This observation would appear to prove that the matters of these intestinal concretions may, as one might have anticipated, be introduced directly by the aliments into the digestive canal.

ORIGINAL CONTRIBUTIONS.

CONTRIBUTIONS TO THE MEDICAL TOPOGRAPHY OF THE MEDITERRANEAN.

By WILLIAM THOMPSON KAY, Esq., Assistant-Surgeon of the Plymouth Division of Royal Marines.

"THE GRAND OBJECT OF ALL TRAVELLING IS TO SEE THE SHORES OF THE MEDITERRANEAN ON THESE SHORES WERE THE FOUR GREAT EMPIRES OF THE WORLD—THE ASSYRIAN, THE PERSIAN, THE GREEK, AND THE ROMAN. ALL OUR RELIGION, ALMOST ALL OUR LAWS, ALMOST ALL THAT SETS US ABOVE SAVAGES, HAS COME TO US FROM THE SHORES OF THE MEDITERRANEAN."—Samuel Johnson.

DIVISION I.—SYRIA GENERALLY, AND BEIROUT PARTICULARLY.

CHAPTER I.

SYRIA.—Its Situation, Name, Extent; Divisions, Ancient and Modern; Physical Characters; Productive Industry; Manufactures; Civil and Social State; Climate; Diseases; State of Medicine and Surgery; Works on the Topography, Natural History, &c. of Syria.

SYRIA is a province of Asiatic Turkey, called by the Arabians *Barr-el-Sham*, bounded on the north by Mount Taurus and its branches, which divide it from Asia Minor; (a) on the east by Diarbekir and the Euphrates; on the south by the Arabian Desert; on the west by the Mediterranean.

Name.—The original name of the country was *Aram*, from *Aram*, the youngest son of Shem; but the Ionians, who frequented these coasts after the Assyrians of Nineveh had reduced the country to be a province of their empire, about the year 750 B.C., corrupted the word *Assyria*

into *Syria*. Some have said that it derives its name from *Syrus*; while Richardson ascribes it to *Suri*, a delicate and beautiful species of rose, for which the country has always been famous, hence Suristan, the land of roses; (a) and *Lem-prière*, to *Sora* or *Tyre*. (b)

Extent.—Syria is estimated to contain about 50,000 square miles, and extends from 33° 20' to 34° 50' north latitude, and 36° 20' to 37° 20' east longitude from Greenwich.

Divisions, Ancient.—In the time of David it was divided into several petty kingdoms, the names of which occur in the sacred writings. (c) These seem afterwards to have been reduced under subjection to the four principal ones, Zébah, Damascus, Hamath, and Geshur. Afterwards the whole country was divided into two parts only, viz., Coelo Syria, and Phœnicia; though the Phœnicians, Idumeans, Jews, Gazites, and Azotites, or the whole country of the Philistines, were included. After the death of Alexander, Syria, in the great extent of the word, was divided into five large provinces, viz., Comagene, the Seleucide, Coelo-Syria, Phœnicia, and Judea. Ptolemy, however, subdivided these, and in Syria Proper reckons only Comagene, Piefia, Cyrrhestica, the Seleucide, the Cassiotide, the Chalybonitic, the Chalcidic, the Aseméne, the Laodicene, the Mediterranean, Phœnicia, Coelo-Syria, and the Palmyrene. (d) By a change which took place in these divisions, a large province, formed to the east by the Euphrates, was known under the name of Euphratensis.

Comagene was the most northern part of Syria, extending north-east between Mount Amanus, from the south-west to the north-east; Mount Taurus to the north; and the Euphrates to the east and south.

The *Euphratensis* extended along the Euphrates, the course of which was here from north-west to the south-east, having a chain of mountains to the west.

Pieria comprehended the town of Seleucia, named Pieria, from the adjoining mountain Pierius, which formed a small peninsula towards the north. At the extremity of this coast was the rock denominated *Rossicus Scopulus*; and upon the northern coast of the peninsula was the town of Rhossas or Rhoss; west of Rhossas, and at the mouth of the Pyramus, was *Agæ*; and between the mountains and the sea, the strait called *Syria Pylæ*. The gulf bore the name of *Issicus Sinus*, from the town of Issus, situated on the northern coast, and belonging to Cilicia. On the eastern coast were Myriandrus, or Alexandria, Alexandria-Cata-Issus, and Alexandria towards Issus, or Alexandressa. In the midst of a valley, near a lake north-east of Antioch, and on the course of a river, was a town called Hieracome, and more to the south, on a mountain, the fortress of Gindarus; to the west was Geophya, on a small river, and south-west Pagre, or Bagias. At a small distance to the south was Antioch, on the Orontes; and further south was the place called Daphne, now *Blit-el-ma*. Towards the east was Imma, or Harem; and in ascending along the Orontes was a fine valley, having to the west Mount Cassius, upon which was a temple, in which were situated Platanus, or Blatanus; and a little further to the south, Baccala, or Bakas, since called Seleuco Belus (Shagr), which took its name from Mount Beluz, which almost shut up the valley on the south.

Cyrrhestica lay to the east of Antioch, and was watered by the Chalus, or Koeic; to the north were Debs or Ain-tab, and Ciliza or Killa. Here were also Chaonia, Abafara, on the north-east; to the south-east, Regio or Sejour; and nearly south of Cyrrhus, the small town of Aza or Ezaz; and south-east, Thura, since Artas or Ikerib.

The *Seleucide* comprehended the towns that lay on the seacoast: such were Marathus or Marakla,

(d) "Encyclopædia Britannica," "Syria."

Balanea or Balinas, Paltus, Gabala or Gebileh (Djebail), and to the north-west, on a small promontory, Laodicea-ad-Mare, or Laditcheh. The tongue of land which advanced to the north-west, was called Chersonesus, having at its extremity Cape Zialet, and upon the northern coast a small fortress called Heraclaea, or Meintaburg; and at a small distance towards the east, a small place called Cathala. At a small distance towards the north, on the seacoast, at the northern extremity of a small peninsula, was Pseiddiam. On the south-east was the isle of Melibsea.

The *Cassiotide*, so called from Mount Cassius, was south of the mouth of the Orontes.

The *Chalybonide* was south of Cyrrhestia, and north of Chalcidice, so called from Chalybon or Berrisa, now Aleppo. North was Miasena, east Bannis, and Thilauri in the mountains.

The *Chalcidice* lay to the south, and joined Assamene. It took its name from Chalcia, situated at the place where the Chalus discharges itself into a small lake. To the east was another lake which, from the saltiness of its waters, was called Lacus Salsus, and on the bank of which, to the north-east, was Gabala, or Gebul and south-west, Thelmenissus or Sernum.

The *Assamene* lay to the north of Laodicea, and was traversed by the Orontes, from south-east to north-west. Here were situated Larissa or Shizar, on the Oropetes; Assamea or Famieh, on the bank of a lake to the south, and surrounded by a lake; to the north-east of Assamea were Murre and Androna; to the east, Cassure and Theleda.

The *Laodicea*, or *Laodicene*, lay towards the north. Here were situated Laodicea-ad-Libanum; to the east, Emesa, where was a celebrated temple of the sun, to the north, Epiphania, called Kamah; to the west, Raphamea or Rasineh; to the south, between the mountains, Lybun; north of Lybun, and north of Raphamea, Demetrius or Akkar, north-east of this last place, Carion; and north-west, upon the Eleutherus or Nahr-el-Kibbir, Mariamme.

Phoenicia was bounded to east by Libanus, and lay to the north of Judea. Sidon was its metropolis, and several other towns of eminence were included in this division. viz., Tripolis, Byblus, Berytus, Tyrus, and Palastyrus.

Cœli-Syria formed the southern part of Syria, between the Libanus and Anti-Libanus. Its principal towns were Damascus, Abyla Lysanie, Soana, Paulas, Helopolis (Baalbec), &c.

The *Palmyrene* was the eastern part of Syria, so called from the famous city of Palmyra (Tadmor).

Syria of Damas extended to the east, along the Libanus, and had Damas for its capital. *Syria of Emath* had Emath on the Orontes for its capital. *Syria of the Two Rivers*, or Mesopotamia of Syria, in Hebrew, Aram Nahazaim, was comprised between the Euphrates and the Tigris. *Syria of Maacha* extended on the side beyond Jordan, and was given to Manasseh.

Palestine was called Syria when it was subject to the Kings of Syria. *Syria of Rohole* was that part of Syria of which Rohole was the capital. *Syria of Soba*, called also Sobal, constituted a portion of Syria, the situation and extent of which are not now known. *Syria of Tob* lay in the vicinity of the Libanus: but its precise limits are not ascertained.

The Roman province of Syria included the whole of Judea *Modena*. It is now, including Palestine, divided into the pashalics of Aleppo, Tripoli, Sidon, Acre, and Damascus.

PHYSICAL CHARACTERS: GEOLOGY.—This country is, in some measure, only a chain of mountains, which distribute themselves in various directions from one leading branch, thus causing that variety of climate for which it is distinguished. The great mountain range, known by the general name of Libanus, extends from the parallel nearly coinciding with the mouth of the Nahr-el-Bard, about ten miles north of Tripoli, to another corresponding with the mouth of the Kasnieh, between Sour and Saida (Tyre and Sidon). These mountains are

parted throughout their whole length into two branches by the fertile valley of the Bekaa, the ancient Cœli-Syria; the western branch is the true Libanus, in contradistinction to which the eastern branch is called by Europeans, Anti-Libanus—a name unknown to the inhabitants. The length of this range is about ninety English miles, and its breadth from twenty-five to thirty. The space included within these limits is divided into ten districts, possessing several little towns, and between six or seven hundred villages. The rock that constitutes it is chiefly limestone, almost as hard as marble, which hardness increases as you advance northward, till, in the mountains near Antioch, it is almost a perfect marble.

Syria abounds in volcanic appearances—some important only in their geological relations; others also historically so; and the southern part, through which the Jordan flows, is a complete volcanic country. At different periods very extensive areas have been desolated by the convulsions of nature, attended with great loss of life and destruction of cities. History affords us direct evidence of the extensive ravages committed by earthquakes, in Aleppo, Tripoli, Sidon, Acre, Antioch, Baalbec, Laodicea, Berytus, &c.; and subjoined is a table of the most important that have happened.

A Table of Syrian Earthquakes.

Date.	Remarks	Number who perished
May 30, 526	Destroyed the greater part of Antioch	950,000
July 9, 551 (a)	Berytus destroyed.	
1169	Successive shocks for four months	
1203 ..	Destroyed Hama and many cities, and filled up the valleys of Libanus.	
October 30, 1759 (b)	Safed laid in ruins. Antioch, Baalbec, Acre, Tripoli, &c. were laid in ruins.	30,000
August 13, 1822 (c)	Aleppo, Antioch, Biha, Grazer, and every village and cottage within the pashalic of Aleppo, were destroyed.	20,000
January 1, 1837	Shook the whole of Syria.	5,000

In the earthquake of 1822 no less than twenty thousand persons lost their lives, and many more were maimed; and the violent shock which devastated Syria in 1837 was felt in a line of five hundred miles in length by ninety in breadth; (d) deep rents were caused in solid rocks, and more than six thousand people perished, and new hot springs burst out at Taberesh.

The chief part of the neighbourhood of Beirut and Libanus is composed of granite, gneiss; mica slate and clay slate on the higher parts; while resting upon and forming the lower ranges are extensive deposits of secondary limestones and sandstones. The limestone abounds with organic remains, and in the neighbourhood of Djebail, fish of the genus *chatodon* are common, and *odontopetra*, *asteria*, *entrochite*, *strobili*, *schmides*, *madriporites*, &c. Resting on the limestone are deposits of tertiary rocks.

Lebanon is said to be rich in mineral productions, and iron is wrought in one or two places, as in the hills of Judea of old (e). Lead and pitch are also found in the neighbourhood Beirut.

The accretions of land on parts of the Syrian shores where rivers do not enter may be attributed to the current of the Mediterranean drifting the sediment of the Nile to the eastward (f).

The soil is very variable. In the plains, near the coast, it is sandy; in the mountains, very rich, abounding with oxide of iron, carbonate, limestone, and in many parts coal and volcanic substances. (a)

The analyses of several soils, from the most fertile parts of the country, obtained during my visits to the places, afford the following results:—

1.—Surface of the Plain of Bealica.	
Alumina	24.7
Lime, carbonate of	16.4
" sulphate of	0.4
Magnesia, carbonate of	1.6
Organic matter	11.3
Silica	28.6
Iron peroxide	13.7
Hygrometric matter	1.3
	100.0
2.—Soil from the Banks of the Nahr-el-Laban	
Alumina	12.0
Lime, carbonate	47.5
" phosphate	0.3
Silica	34.2
Vegetable matter	4.1
Hygrometric matter	1.9
	100.0
3.—Soil from Salayah, Damascus.	
Lime, carbonate of	86.0
Alumina	7.0
Organic matter	5.3
Hygrometric matter	1.7
	100.0
4.—Rich Soil from the Libanus (Bryndina)	
Alumina	23.9
Lime, carbonate of	4.2
" sulphate of	1.1
Magnesia, carbonate of	a trace.
Salts of potash and soda	0.3
Organic matter	13.0
Silica	34.1
Iron protoxide	19.4
Hygrometric matter	3.9
	100
5.—Soil of the Gardens of Beirut.	
Alumina	48.0
Lime, carbonate of	28.1
Magnesia, " "	4.0
Soda, nitrate of	0.3
Iron protoxide	5.4
Organic matter	7.9
Silica	15.0
Hygrometric matter	1.3
	100.0

Like most countries composed of calcareous materials, and which have been visited by successive earthquakes, Syria abounds in caves, stalactical formations, and deep recesses in the limestone. Near the source of the Nahr-el-Kelb is a natural bridge, considered, and deservedly so, the greatest curiosity in the neighbourhood, or even Syria. It is called by the natives Djessar-el-Khadjer, and is of the following dimensions.

The span	180 feet.
The spring	140 feet.
The breadth	140 feet.
Height from the water to the summit	160 feet.
Depth of the keystone	20 feet.

MOUNTAINS.—Syria is divided into two distinct portions by Mount Libanus, whose highest peak is 11,050 feet above the level of the sea, and perpetually crowned with snow.

In the north the principal mountains are Djebel, (b) Khneb-Djebel Akkar, and Djebel Amanue.

In the south, Anti-Libanus and Mount Hermon.

In the east, there are the Sheball and Umanran hills.

(a) Captain Frankland's "Travels," vol. ii., p. 168.

(b) Djebel signifies a mountain; Nahr, a river; Bahr, the sea or lake; Râs, the head or cape.

She had been out on the previous evening, and then for the first time felt her face flushed and warm, next morning the eyes were inflamed and tender, and the usual catarrhal symptoms had set in. On Tuesday the eruption was distinct upon the face. As the cough was harassing, I ordered a mucilaginous mixture, with syrups of squill and saffron which effectually relieved it.

On Wednesday, the 12th, the eruption was well out over the trunk and extremities, complaints of nothing except of the excessive heat of the surface of her body.

On the 13th the eruption had nearly faded away, and in every respect our patient was going on favourably. At eleven P.M. I was summoned to attend, labour pains having commenced since four o'clock, and continuing with regularity and increasing in intensity every ten or fifteen minutes.

On a vaginal examination, the os uteri was found dilated to the size of half-a-crown, the head of the child presenting and low down, the bag of membranes entire.

Labour progressed favourably until half past two A.M. of the 14th, when, the soft parts being fully dilated and the membranes protruding, distended largely with the liquor amnii, I allowed the waters to escape, which were in great abundance, and at an unusually high temperature. Half an hour afterwards she was safely delivered of a fine healthy male child, full-grown, his skin was thickly covered with venous casusum, but when washed presented a natural and healthy appearance.

15th Both mother and baby doing well, the latter is exceedingly quiet, and drinks well. There is a wrinkled state of the skin extending from the root of the nose over the eyebrows, was observed to sneeze, and his shirt became occasionally.

16th Mrs C slept well last night until early this morning, when she was disturbed by the baby, the latter is heavy and drowsy, present the colour of his face is rather yellowish than red, but the attendant said that they observed distinct spots upon his face and neck an hour before my visit, continuing to sneeze frequently, breathes free, stools natural.

17th 1p day, distinct blotches of measles are visible on the cheeks, neck, and shoulders, the catarrhal symptoms continue, but not severe, the cough frequent, secretions natural.

18th The eruption has almost disappeared off the baby, his mother has a long supply of milk, of which he partakes freely.

19th Both mother and child progressing most favourably, which they have continued to do up to this date, the 27th of May.

The above case I think is interesting in a double point of view. First, as proving the innocuousness of measles to the healthy female even at the close of utero-gestation. And secondly, as establishing the fact that measles are not contracted by the infant *in utero* but may be communicated to it, at birth, by its own mother, and afterwards run their usual course.

30, Harcourt-street, Dublin

OBSERVATIONS ON THE ACTION OF MERCURY IN INFLAMMATION, AND ITS EFFECTS ON THE SYSTEM

By HENRY SMITH M.D.

Late House Surgeon to King's College Hospital

(Continued from page 271)

I have, in my former papers, endeavoured to lay down a theory of the action of mercury in inflammation, have reviewed those forms of inflammatory diseases in which it should be given, and those forms in which it should be withheld, and have made some remarks upon the mode of administering it, and upon those immediate effects which often arise during its exhibition. It is now shown that they are accidental, of by no means an unfrequent nature, and that they prove prejudicial to the patient, and embarrassing to the practitioner. Before I take leave of this subject, then, I think it right to make some remarks

on the best mode of preventing these accidents from taking place, and of counteracting them when they have taken place.

Excessive salivation and severe purging are the accidents I mentioned, and, to speak of the first. It has been shown, from a few cases I mentioned, that this is attended sometimes with a fatal result, or, if not so, at least with dreadful suffering and, perhaps, lasting disfigurement, and consequent misery. Since that portion of these observations which contained the above cases was written, I have had an opportunity of seeing a shocking instance of deformity and suffering from the effects of violent salivation in a young man who was a patient in the King's College Hospital. The jaws had become permanently closed, and the greater portion of the lower lip had been destroyed by sloughing, consequently the saliva could not be retained, and was running off from his mouth. This had happened twelve years ago and he applied to the hospital to have the benefit of Mr. Ferguson's operation, who has performed the operation recommended by Mr. Syme, for restoring the lip.

Excessive salivation is doubtless apt sometimes to arise during the exhibition of mercury, where no want of caution has been shown, either from a peculiar susceptibility of the patient to its influence, or from a large dose having been taken at once, but many cases are owing to a proper want of caution on the part of the practitioner, or from some ailment in the part of the patient. And I think, therefore, that many of those distressable cases of violent salivation may be prevented by watching carefully the effect of the remedy. The first symptom of salivation should be strictly noticed, and the remedy should then be continued according as the disease which we are treating is more or less slow. As a general rule, when the system is affected the dose should be diminished as small a quantity would be sufficient to keep up a circumscribed action, and we can very easily strengthen or lessen its action, according to circumstances indicate its use, by altering the frequency and strength of the doses, and it should be collected that pushing on a furious salivation will do no good, if a far but moderate action of the remedy has failed. By attending to these points, we shall be spared the painful sight of patients who are made from some diseases perhaps not very severe themselves with greatly enlarged salivary glands running out of their mouths and hardly able to articulate plainly, or, if they can speak cursing, the remedy a worse than the disease, and speaking in no measured terms of the doctor who has been giving it.

I, however, except a hygienic diet set in with all its common evils and annoyances, we must use those remedial means which our art has afforded us with the view of neutralizing the poison both locally and generally, and they must be employed with more or less vigour, according to the nature of the case.

Generally speaking, in the severe cases, there is great inflammation of the cheeks and mouth, and, moreover, from this cause there is inability to open the jaws. If such should be the case it would be advisable to apply a few leeches on each side of the face, and afterwards to foment continually with cloths saturated with warm water or a decoction of poppies, this will abate the inflammation and relieve the patient of the excessive pain which this condition produces. At the same time some astringent and antiseptic lotion should be used with the double object of constringing the relaxed and swollen parts inside the mouth, and correcting the abominable fetor and the disposition to slough which is attendant upon such cases.

Various remedies are used. Dr. Watson, in his lectures, speaks highly of brandy and water, and I have in more than one instance employed it with benefit, a good preparation is a mixture of alum and chlorinated soda 3ij. of the former and 3j. of the solution of the latter to 3viij. of water; but the strength must vary according to circumstances, if there is much ulceration, a strong solution will give unnecessary pain. Oak-

bark, nutgalls, and tannin are also valuable remedies, and particularly the latter, as it is a powerful astringent. If there is inability to open the jaws, and the mouth is clogged with a viscid secretion, the lotion should be injected with syringe, and warm water should be frequently thrown in in the same manner to clean this nasty stuff away. But local measures alone will not suffice the constitutional symptoms, which are severe and in some cases alarming, should be attended to, and we must endeavour to get the poison excreted from the system by the various purgative organs. In general there is extreme depression, accompanied with quickness of pulse and nervous symptoms. These, then, obviously indicate measures of support, and it will be requisite to give it liberally. Any bland nourishing material mixed with wine may be given occasionally, and a decoction of bark, or quinine be prescribed, and these remedies may be increased or diminished according to circumstances.

Sometimes, as I have before said, there will be the greatest difficulty in getting food into the mouth, so much pain is experienced on attempting to move the jaws. If this be the case, the attendant must carefully separate the jaws and supply the nourishment and medicine by means of a feeder or spoon. In more than one instance have I been obliged to do this myself, when it has been impossible for the patient to do it. For the purpose of getting the mercury more quickly out of the system, or neutralizing its effects, we must use certain medicines which act on the secretory organs, or which combine with the mineral. The bowels should be well purged by some vegetable or saline medicine, and they should be kept open if the patient is not too debilitated. Various remedies have been recommended, which are found to act as antidotes to mercury either by acting on the secretions in some manner or by combining with the mercury and neutralizing its power. Tartar emetic, acetate of lead, opium, have been given and spoken well of by some. The former acts beneficially, by exciting the skin, the latter, by checking the secretions of the mouth and constringing the parts. There is one remedy, however, which appears to possess considerable influence in removing salivation, and one which I think is not universally known, I mean sulphur; by referring to Mr. Cullen's works I find that he recommended it several years ago. In what manner it acts we are not able exactly to tell, but it is highly probable that it enters into combination with the mineral, and forms a sulphuret, which is in part preprepared, moreover, it acts as a purgative and also goes off by the other secretions, particularly the skin. I have had opportunities of using sulphur for ptyalism, and I have seen it used by others, and certainly, in the majority of cases, decided benefit occurred. The only objection I have noticed, is the fact that it sometimes irritates the bowels very much. I used it in a case lately, when I was obliged to suspend it for this reason. I would strenuously recommend it to those who may meet with a troublesome case of salivation. Mr. Allison has found out that chlorate of potash has a most beneficial influence over mercurial salivation, and he has tried it in numerous cases.

These, then, are the means which it would be advisable to employ, should we meet with a severe case of this kind of disease, and they will in the majority of instances relieve the distresses of the patient and hasten his cure, nevertheless, in some cases, bad results will happen cicatrization of the parts will take place and contractions follow, and the motions of the jaws be much limited, or there will be a loss of a greater part of the lower lip, and consequently an uncomfortable flowing away of the saliva, these are accidents, however, which are now rare, and which happen for the most part, perhaps, when there has been some neglect.

Sometimes, after the acute state is over, and the patient has become convalescent, the gums continue very sore, and the affection still remains in a less degree. This will be found to happen

amongst the lower orders, who are dirty in their habits, and neglect their teeth; in such a case we shall find them incrustated with a quantity of filth, which keeps up the irritation: by removing this with a proper instrument, and using plenty of water and some astringent lotion, the cure will be effected.

The purging which sometimes takes place on the administration of mercury I will next consider, with respect to those measures which are liable to prevent and correct it; and these are important points to consider, as this occurrence is extremely troublesome, and likely to suspend our efforts in the cure of disease, for some time at least.

In the first place, whatever preparation of mercury is going to be used, if possible, the bowels should be well cleared out previously by some aperient which will effectually do this without irritating them much. The mercury should be carefully combined with opium, and the dose of the latter should be increased in quantity if necessary. If any griping ensues we may suspect that the mercury is about to act on the bowels; therefore, we should either suspend it, if we can, or, if not, we should diminish the dose, and our object may be gained without any inconvenient occurrence taking place. But nevertheless, notwithstanding great care on our part, the mercury will detract to the bowels, and produce the most severe and harassing diarrhoea, and even dysentery, and it now becomes our duty to correct and restrain it. The mercury must be left off; an opiate and starch enema be given, and a draught containing some aromatic confection, olive oil, and some laudanum; this will check it immediately. If the mercury is necessary, we had better use it in the form of ointment, as, in all probability, the use of it internally will be attended with irritation of the bowels again; and, should this be the case, it will be found extremely difficult to salivate the patient.

John Hunter, thinking that the purging was produced by the mercury uniting with the acids in the intestines, and thus forming an irritating compound, advised the employment of alkalis to correct this morbid state; and I have heard it remarked, that all purging may be effectually prevented by giving, after each dose of mercury, an ounce of chalk mixture.

I have now brought to a close the observations I had intended to make; but, since I had begun to put them together, my attention was attracted to a paper in the *Lancet* of April 24, by Mr. Holmes Coote, which had the object of inquiring into the efficacy of mercury as a remedy for syphilis, and of showing that it is not the power of radiating this poison from the system. For this purpose he has related numerous cases of syphilis which, after it had been proved that the patients had taken more or less mercury, were followed sooner or later by secondary symptoms; and he ends his communication in these words:—"I confine myself to the conclusion which these cases seem to warrant—namely, that whatever power mercury may possess in arresting the progress of syphilitic ulceration, or in removing some secondary affections, it is wholly inefficacious in eradicating the venereal poison; and, moreover, that when carelessly administered it injures the general health, and is capable of exerting a most injurious influence, by which the subsequent symptoms resulting from the infection may assume an infinitely more to midable and intractable character."

Mr. Coote, with a view to obtain truth, has followed the proper mode of investigation, which will alone bring good results, by collecting a number of cases, observing them, and reasoning upon the facts observed; but, at the same time, I think he has failed in convincing his readers of the truth of the opinion he asserts—that mercury is wholly inefficacious in eradicating the venereal poison; and that he will not shake their faith in a remedy which has been handed down from generation to generation as a specific against one of the most dreadful scourges of mankind. We have not enough specifics as yet, therefore let us not hastily reject those which we now possess.

Mr. Coote collected his cases, as I suppose, from hospital patients—in and out—and appears to place perfect reliance on their statements; but every one who has seen much of hospital patients, and particularly those who labour under the venereal disease, must be aware of the great difficulty there is in obtaining correct information on a point which even their small sense of shame will forbid them to give.

Moreover, Mr. Coote, I suppose, had not many of the patients, when affected with primary symptoms, under his observation at the time, and, therefore, he is unable to tell the manner in which they were treated; he knows certainly that they did take mercury, but he does not know (or, at all events, he does not say he does) how the remedy was administered: whether those precautions which are necessary for the proper action of mercury were used, and to what amount, and in what time the system was affected, and whether or not that proper attention was paid in the administration of this remedy which must be observed in the treatment of syphilis. In some of the cases mentioned Mr. Coote gives the particulars; for instance, Case 13—"A woman took mercurial pills at the request of her husband, and suffered a profuse salivation." Case 17—"A sailor, of his own accord, took two or three hundred pills; his health suffered severely; but, abstaining from mercury, he got well; on landing he had rupial sores." In another case the mouth was but little affected; and in Case 20, a patient took mercury for phagedænic sore, and, this not healing, he had secondary symptoms.

Now, I have no doubt every one will admit that, although a salivation may be excited by mercury, that is no reason why a sore should be healed and secondary symptoms be prevented, particularly if this salivation has been induced rapidly and severely, and not according to the rules which ought to be followed in the administration of mercury. Mr. Coote must be aware that symptoms similar to those produced by the poison of syphilis will be produced by an excess of mercury, or by this drug being given incautiously and at improper periods, and, moreover, that it is very difficult to distinguish the two diseases; it is probable, therefore, that the symptoms observed in those cases, when a profuse quantity of mercury had been taken, was as much owing to this cause as the venereal poison—in fact, to a combination of the two. I am persuaded that Mr. Coote, from having held the position of house-surgeon to Bartholomew's Hospital, must have had cases under his care where the symptoms, after a large quantity of mercury had been injudiciously given for syphilis, were so difficult to be rightly understood that he has hesitated what course he ought to pursue, whether to give mercury or to abstain from it altogether. I am sure I have seen cases in King's College Hospital (where I have had an opportunity of observing a great deal of syphilis) in which the symptoms were attributable not to the venereal poison alone, but to the influence of mercury taken to an unwarrantable extent. It is from my own observation of these cases, and from the experience of those who have written largely upon this subject, that I have come to the conclusion that symptoms similar to those produced by the poison of syphilis may occur from mercury, either taken to an immoderate extent, or not in sufficient quantity, or with proper attention to those rules which should be always followed when this powerful remedy is being taken.

If Mr. Coote could bring forward a number of cases where it could be seen that mercury was given cautiously, and according to the rules of art, and where every necessary concomitant assistance for the eradication of the poison was followed, and secondary symptoms subsequently showed themselves, then he would have sufficient reasons to form a strong opinion on the subject; but, until he does so, I think he will fail in establishing his opinion, "that mercury is wholly inefficacious in eradicating the venereal poison."

To show how necessary it is to observe careful

rules in the use of mercury, and not be content with salivational alone, I will quote the words of a late celebrated surgeon who paid great attention to this point. Mr. Colles, after speaking of those precautions which are necessary in the administration of mercury in syphilis, says—"I have been thus particular in stating at what period the surgeon should wish pyralism to commence when using mercury for the cure of primary symptoms, because I am firmly convinced that he cannot count upon a cure if the salivation occur at a period much different from the above-mentioned period: for, should he, be suddenly agitated, and even though not profusely, it will yet leave the disease uncured; perhaps the primary disease may be cured; oftentimes it is not, but, at all events, the secondary symptoms will not fail to make their appearance, sometimes in full vigour, though often under a more subdued form."

Again, Dr. Graves, who has paid much attention to this subject, says (although a non-mercurialist)—"The venereal poison produces a peculiar train of primary and secondary symptoms; the mercurial another, and that not very dissimilar. Experience has proved that in general the venereal symptoms yield to the action of mercury; but occasionally this is not the case, in consequence either of some constitutional peculiarity, or an injudicious use of this mineral; and thus the constitution labours under a modified disease resulting from the combined effects of the two poisons."

ERGOT OF RYE IN HEMORRHAGE.

By W. W. DOHERTY, M.D.

Ex-Member and President of the Royal Physical Society, Edinburgh University; Lecturer in Midwifery; Member of the Dublin Obstetrical Society; Physician to the Dispensary; Isle of the Sisters of Charity, Edinburgh; and to the Guild of St. Joseph, Edinburgh.

How far, if at all, interesting to your readers the following case may be, I beg to submit it on account of its novelty. I am not presuming too much when I say it is the first case on record of the kind where the same treatment has been adopted. I would have refrained from the performance of this light task had I not observed allusions to M. Bonjean and Dr. Chevalle, of France, in the journals, in connection with the introduction of the use of seculi cornutum (ergot of rye) in external and internal hemorrhage—or, in other words, its use as a styptic externally, and its value in hemoptysis and hæmaturæ. I am well aware it has been little, if at all, used in this country except in uterine hemorrhage. This much I know, after conversing with many—all, I may say, of the leading men in Edinburgh—that in only one or two cases have they ever heard of its employment. A medical gentleman in Fife, I heard from my friend Dr. Sumner, tried it in hæmaturia, but, I think, unsuccessfully, owing to complication of disease and advanced age. I have taken pains to make strict inquiry how far it may have been used, but have failed to find its having been resorted to except in uterine cases in this country; and in which I believe there is no person of the present day possessed of any information who will question its utility. On the 6th of June, 1842, I was requested to visit Mr. M'L., who had been seized with an attack of hæmaturia two or three days previously. On my visit I found Mr. M'L. in an exceedingly weak condition—the pulse almost imperceptible; countenance anxious, with, expressing the abdomen, very considerable pain and tenderness. The first object I had in view was to remove this exhausting pain; and with difficulty I have prevailed on his friends to apply twenty-four leeches to the epigastrium, they fearing that his death, by their application, would be accelerated. The most powerful astringents immediately were had recourse to, including the mineral acids, sulphate of copper, gallic, Ruspi's styptic, alum, kino, and...

cha and epium, in combination with kino, &c., but without any apparent diminution in the discharge of blood, which still continued to flow in fearful rapidity and profusely. The leeches removed much of the pain, and he expressed himself satisfied with their application. The quantity of blood vomited I could not well ascertain; I had sufficient proofs of it being large from the appearance of the vessels in which it lay, the saturated condition of the bedclothes, and the reports made by those who witnessed it: in fact, to describe it as I saw, much less to speak of it as represented, would be looked on as exaggeration. My endeavours to arrest the hemorrhage by the usual means seeming ineffectual, I thought it right to have the advice of some eminent men, and I suggested this to the family. Professors Lizars and Allison were sent for, but owing to engagement, the latter did not come. Professor Lizars and I continued our attendance until Friday morning, when, for the last time, we saw him together at eight o'clock A.M. From the commencement our hopes for his recovery were far from sanguine, in fact we despaired of him, considering the time which had elapsed before advice was had, and the alarming symptoms which accompanied the attack. I had once used ergot, but had not satisfied myself of its power in such a case, and was determined, should another again arise, to try it, and on frequent occasions spoke of it to many medical friends, who seemed to think the power of ergot in checking hemorrhage did not extend beyond the uterus, and consequently in this case would be useless. Is the power of ergot confined to muscular structure, as the uterus? I say no, but is extended to cellular structure, as to this case. Here there was no hope of recovery, and I suggested to Professor Lizars to make a trial of the ergot. He at once consented, and I prepared an infusion of three drachms to six ounces of boiling water, ordering two tablespoonfuls every half-hour to be given punctually. As I mentioned before, Professor Lizars did not again see him, nor did I on my leaving with him ever expect to see him alive. On leaving I promised to return in about three hours. He expressed a strong desire for me to remain, but other engagements prevented me, and I pleaded my excuse with great regret.

At the time appointed I returned, and, to my surprise and pleasure, found the hemorrhage had ceased. Strange as it may appear, the pulse became quite elevated without any stimulant. I forgot to mention in its proper place, that the extremities, as well as the entire body, were cold and clammy in the morning when I left, as throughout, notwithstanding heat to a high degree had been applied to the feet, air having been freely admitted into the room, where atmospheric pressure had been great previously, the whole surface of the body soon assumed as natural a heat as could have been desired. A second attack of pain (abdominal) returned next morning, but, although inclined to repeat the leeches, I applied an instant blister, as I feared more than enough blood had been already lost. I gave him five grains of Dover's powder, and ordered another dose in three or four hours, and to be repeated under certain circumstances. Same day there was a slight return of the discharge, which caused a good deal of alarm; I repeated the infusion, the hemorrhage was again stopped, and the abdominal pain yielded to the blister. Dr. Mist, of Lebanon, uses ergot, and has not found it lowering the pulse. He was called into a case of menorrhagia, Mrs. C., who was attended by another practitioner, who used the "tampon" ineffectually, he thought "the debility was considerable,"—these are his own words; it was a favourable case for the ergot; used in five-grain doses; reaction was the result, and the hemorrhage ceased. Miss L. was attacked similarly; respiration difficult, extremities cold, pulse small and weak; the same treatment was observed, the same result followed; "the hemorrhage was checked after the third powder."—*New York Medical and Physical Journal* (No. 36).

This medicine has been extolled by many; and condemned by many too, very unjustly. I have heard it condemned by men who acknowledged, nevertheless, its use. For my part it is not with me such a favourite remedy as to induce me to apply it on every occasion, but I would infinitely prefer it internally to creosote, as recommended by Sir P. Smith.—*Dublin Journal*.

Yet, on the other hand, having had an experience of some years of its powerful astringent qualities, I would not consider myself without blame were I to conceal the result of that experience from the profession, believing that by its agency the life of the patient to whom I now refer, and other lives, have been saved. Mr. M.L. never had a third attack; he is now well and in the enjoyment of most excellent health. The late Dr. Abercrombie witnessed its use in another patient of mine, Gilchrist, a man residing in the High-street. I trust that in giving this case it may be received as it is offered. It is done, first, to prove that this medicine may be employed with advantage, even when there is great prostration, in other than uterine hemorrhage. My object is not to extol it beyond its merits, but I think it only fair to give it a trial; and to those who place no confidence in its efficacy, I would respectfully say, what harm can it do when the usual remedies fail, and death stares you in the face? I have only to look back a few years, and find its use in obstetric cases abused or questioned. Further, I will find that such men as Paulet, Decandolle, and Wildenow have disagreed in regard to its qualities, its actions, and the cause of its production. That it has long been known in obstetric practice since 1600 is quite well ascertained, and yet is it not strange that prejudice has prevented its use in cases such as I refer to? Mitchell (England), who uses in menorrhagia, will not agree with Mist (Lebanon), the latter admitting it *per se*, the former denying its efficacy unless combined with acetate of lead.

As I mentioned one reason for intruding myself on the attention of the profession, I may state another—viz., as it relates to its entire efficacy without combination with any other astringent; that it is in itself a most powerful astringent, which can be exhibited in such cases without any bad consequence resulting; and thirdly, to show that I have used it with success in this country before it was tried, or at least recorded, in France as having been resorted to. The last may appear somewhat a selfish reason, but on that head I will not occupy a line in explanation. I am narrating facts; which, if useful, is enough for my purpose. But there is one thing certain, that to French pathology we owe much, and to local bleeding, in cases like Mr. M.L.'s, the French were the first to direct our attention to its efficacy, yet, in acknowledging this, it would not be fair to permit to pass by in silence, that in France ergot of rye was first used in hemorrhage—not uterine—when, in point of fact, it was used in Scotland long previously—and successfully. The doctrine of hemorrhage has occupied much attention at all times, and practical men of the greatest experience have indulged in views concerning it which have died with themselves, and never have been regarded as sound or scientific. Even the industry of Cullen was incomplete on the subject, many important points being unnoticed in his dissertation.

I will not refer further to the subject of which this communication treats, than by directing attention to the case which is particularly referred to, and to this important circumstance, that "nature seemed not exhausted," as the person who suffered loss of blood to an enormous extent was, in a few days after my visit of Sunday, seen driving his horse and gig through town in his (almost) usual good health, and is now in perfect health.

MAGNETIC DISCOVERY.—It is said that a physician in the south of England has discovered the principle of magnetic force which explains the deviation and dip of the needle.

FOREIGN PRACTICE.

Reported for the MEDICAL TIMES by ALFRED MARK-WICK, Esq., Surgeon to the West-end Central Dispensary, and formerly Lecturer to the Veterinary Hospital, Paris, &c.

CASE ILLUSTRATING PROFESSOR FLOURENS' THEORY OF THE FORMATION OF BONE.

A young man, from twenty-five to thirty years of age, entered the Hôpital Dieu about twelve months since, under the care of M. Blandin, for a fistulous wound on the anterior superior region of the chest, along the course of the left clavicle. M. Blandin probed the wound and discovered that it proceeded from caries of nearly the entire internal half of the bone. Before determining on an operation, he was desirous of trying the effect of emollients and resolutive unguents; the disease, however, continued to make progress, and the patient, who lost flesh daily, was anxious for relief. M. Blandin, therefore, no doubt reflecting on the beautiful results that had been obtained by Professor Flourens, who succeeded in effecting the reproduction of the entire radius in dogs and goats, decided on extirpating the diseased portion of the bone, hoping that by adopting this plan it would be reproduced.

He made an incision along the upper surface of the clavicle, from its centre as far as its internal or sternal extremity, including in this incision the periosteum upon which the reproduction of the bone mainly depends. At either end of this incision he made another at right angles, so as to represent two T's, thus [—], then denuded the clavicle all round, and passed beneath it and the periosteum an instrument made expressly for this description of operation, in order to protect the latter and the surrounding soft parts. He was thus enabled to saw through the bone at its centre without danger, disarticulate it at its sternal extremity, and remove it.

After M. Blandin had terminated the operation with his usual dexterity, the patient, a man of great courage and *sans peur*, requested him to examine carefully the remaining half of the bone, preferring to have it at once extracted than to wait at all anxious, than to have to undergo eventually a second operation. On complying with this request, M. Blandin found that it was necessary to remove the other portion of the clavicle, which he did with the same care and success. The patient recovered in a short time and left the hospital.

In this case we have a confirmation of the beautiful theory of M. Flourens, of the formation of bone; and the result obtained in this instance will be always met with, provided a favourable course be adopted; the best, and undoubtedly the most indispensable, is the preservation of the periosteum. Wherever the periosteum, the envelope, the mould, if I may so express myself, of the bone is preserved, the bone becomes reproduced—a result obtained by M. Flourens in operating on young animals; the bone in these cases being formed in a very short time.

The following, however, are the observations made by Professor Flourens himself:—"We may take away a portion of bone from the periosteum, and it will restore that portion; we may remove from it the head of a bone, and it will restore that head; we may take from it an entire bone, and it will reproduce the bone entire. Consequently, the periosteum reproduces and restores every portion of bone that it is deprived of." * * * "And now, having explained, having proved by so many different experiments, the extraordinary faculty, previously little known, of bone in reproducing itself, may I not hope that this astonishing power will soon prove of great value in the hands of surgeons?"

"Doubtless, no. I appeal to reflecting surgeons—to surgeons who look upon surgery not as a mere routine business, but as a science, a noble science, and who see humanity beyond it."

A conviction, therefore, of the truth of these assertions, which are perfectly original, I believe induced Professor Blandin to remove the whole of the clavicle by preserving uninjured the pe-

into the chest, and of the mischief which might result from its presence in the pleura. Experience has shown that the apprehensions on this score were unfounded, or at least much exaggerated, and that the penetration of air into serous cavities is far less formidable than it had been imagined. For the operation of thoracentesis, however, all fear of this accident may be at once set aside by the use of Rébard's instrument, which precludes the introduction of the smallest particle of air into the pleura. This instrument has been adopted by Professor Troussau, whose operative process we will explain after giving a short description of Rébard's invention. The instrument consists of a common hydrocele trepan, to the canula of which is attached a membranous tube, on the withdrawal of the blade from the canula, the tube closes the orifice of the canula, effectually preventing the entrance of air, without in the least interfering with the escape of the fluid. M. Troussau begins the operation of thoracentesis by puncturing the skin with a lancet on the level of one of the ribs, immediately below the intercostal space to be punctured. The object of the incision being made thus low is obviously to prevent the parallelism of the wound of the pleura and that of the skin after the removal of the canula; the skin is then pressed upwards, so as to bring the incision already performed opposite the central part of the intercostal space, where the trocar is gently passed into the chest, the fluid escapes, and no air can penetrate, owing to the simple and ingenious mechanism above alluded to, and instantaneous relief of course follows the liberation of the chest. Several cases have now been in operation in this manner by M. Troussau and others, with the greatest success. It may not, perhaps, be in all cases advisable to withdraw at once all the fluid contained in the chest. A few weeks since the operation was performed by M. Robert, on a patient at the Hôpital Beaujon, the totality of the effusion was removed, and almost immediately afterwards the patient expired. The only alteration found after death to account for its suddenness was an immense quantity of frothy mucus in the air-passages. Perhaps it is, in the case of death immediately after thoracentesis, which we recorded in vol. xv, p. 265, the fatal termination may be attributed to the sudden removal of a considerable pressure from the lung vessels, by which an unusual rush of blood and induration took place in the central organs of circulation.

Fracture of the Temporal Bone. In fractures of the petrous process of the temporal bone, the issue of a serous fluid through the middle auditorius externus is justly considered as a characteristic sign of the fracture, and its gravity is universally acknowledged. But, on the one hand, the opinions of surgeons on the origin of this serous fluid are extremely various, and on the other, the fluid is not always of the same nature. M. Langue considers this liquid as the serum of the blood, indicative of hemorrhage within the cranium, and filtering through the division of the bone. M. Robert gives to this fluid another source; it is in his opinion the cephalo-rachidian liquid, but the anatomical proofs of this assertion have not been given, on account of the thinness of the rachidian membrane, the laceration of which is absolutely necessary to the escape of the cephalo-rachidian liquid. Chemical analysis has on two occasions shown it to contain a large proportion of chloride of sodium, and very little albumen. Mr. Guthrie was of opinion that this fluid, escaping through the ear, had its source in the cavity of the strachoid. In another set of cases, immediately after a fracture, a discharge of blood takes place from the ear, becomes soon sero-purulent, and finally acquires the colour and consistency of real pus. It would be important to ascertain if the difference of nature of these seral discharges corresponded to a difference in the diagnosis, and especially in the prognosis, of the injury.

After a brilliant career, Messrs. Vigla, Becquerel, Gosselin, Mussy (N.), Kéyer, and Hardy, were named Professors Agrégés at the Faculty of Medicine.

D. McCARTHY, D.M.P.

The Use of the Hair in Animal Economy.—The hair, says Mr. Paget, in its constant growth, serves, over and above its local purposes, for the advantage of the whole body. In that, as it grows, it removes from the blood the bisulphide of protein, and other constituents of its substance, which are thus excreted from the body. Now, this excretion officer appears, in some instances, to be the only one by which the hair serves the purpose of the individual; as, for example, in the foetus. Thus, in the foetus of the seal and, I believe, of most other animals, removed as they are from all those conditions against which hair protects, a perfect coat of hair is formed within the uterus, and very shortly after birth is shed, and replaced by another coat of wholly different colour, the growth of which had begun within the uterus. In these cases it is chiefly as a secretion that this growth of hair serves to the advantage of the individual. The *lanugo* of the human foetus is an homologous production, and must similarly serve in its economy by removing from the blood, as so much excited matter, the materials of which it is composed.

Constipation.—The causes of this disease, Mr. Edward Crook remarks, may be either nervous or mechanical. Amongst the former may be enumerated apoplexy, and other conditions of the brain and nervous system, which appear to paralyze the muscular fibres of the intestines. These may be overcome by appropriate treatment. The mechanical are more likely to occasion permanent obstruction and death. These obstructions may be either within the tube, or produced by pressure from without. Amongst the former may be enumerated intussusception, extraneous bodies introduced by the mouth or anus, biliary or cerebral calculi, ulceration producing thickening or contraction of the tube, intussusception, scirrhus thickening and malignant growth of the mucous submucous tissues, congenital contraction and occlusion occurring at all parts of the canal, fibrous tumours of the muscular or submucous tissue. The external causes are tumours pressing on the bowel, the escape of intestines or omentum from its proper cavity, constituting hernia, dentitions by which producing constriction, the gluing together of the intestine, so as to interfere with their peristaltic motion, twisting of the intestine, abscess occurring on the walls of the adjoining parts.

Soft Cancer involving the Caudal Organs of the Stomach.—Mr. Nottan related to the Bath Pathological Society the case of an individual who, when first brought under his care, suffered from constant vomiting, not taking food, attended with gradual emaciation. No symptom could be detected over the region of the stomach, but the small intestine was enlarged, and the caecum was enlarged, which met with some obstruction at the junction of the sigmoid with the caecum. Mr. Nottan thus united with a month of the patient's death, when it was found that the tumour would no longer pass into the stomach, in consequence of obstruction at the caudal orifice. On dissection, it was found the lower end of the esophagus and the caudal end of the stomach were found involved in an extensive cancerous deposit of the soft or encephaloid kind. The disease had not attacked any other organ of the body. The cause of the obstruction to the passage of the bougie was found to be an ossified condition of the thyroid cartilage, by which the esophagus was pressed backwards and on one side.

Chronic Inflammation of the Cæcum and Colon.—The predisposing cause Mr. Storrs considers to be a relaxed and atonic state of the vascular system, and a highly irritable state of the nervous; the exciting causes—torpor of the bowels, scybalæ, drastic purgatives, and repeated errors of diet. It may not unfrequently be connected with suppressed hemorrhoidal discharges, and tight lacing. The stools afford a good criterion of the nature of the disease—often they are perfect in form and consistency, but pale, coated with mucus, or

or tenacious; occasionally the mucus will appear in small lumps, not unlike lumps of fat, at other times it assumes the form of the finger of a glove. This mucus is uncoloured; sometimes there are scybalæ discharged with it. In this disease all drastic purgatives are to be avoided. A few leeches, followed by blisters, are advisable when there is abdominal tenderness. When inflammation has subsided, the tone of the system is most rapidly restored by a continued exhibition of the citrate of iron. Smart doses of calomel and scammony, followed by castor oil, are useful when scybalæ are suspected; in other cases drastic purgatives should be avoided, and mild injections substituted for them. When the inflammatory symptoms do not yield to leeches and blisters, the linimentum hydrargyri is useful.

Abnormal Conditions of the Blood.—These are arranged by Simon under four divisions—1. *Hyperæmia*, in which fibrine exists in excess—a characteristic of the true inflammatory type of disease. 2. *Hypinæmia*, consisting in a deficiency of fibrine, seen chiefly in fevers of an ataxic type, in passive hemorrhages, and in certain cachectic states of the system. 3. *Spanæmia*, in which the blood is poor in solid constituents, but especially in fibrine and corpuscles. 4. *Hæmochromæmia*, embracing all those states of the blood in which some substance is present which does not exist in the normal fluid, as in diabetes, morbus Brightii, &c.

Cancer.—Th. Walsby has found conium and other narcotics, in the treatment of this disease, do little more than alleviate pain. The only medicine which he has found of real benefit is the iodide of potassium, in conjunction with compression. It afforded the greatest chance of success. It may be given with safety in doses of one twelfth of a grain, and continued for several months, if the precaution be taken to exhibit it about two hours after eating.

Effects of Disease upon Animal Temperature.—The most complete example of this kind of investigation (says Dr. Rankin in his retrospective address) is that of M. Roger, consisting of a careful study of the effects of disease upon temperature of children, the results of which may be thus briefly recapitulated. In *typhus fever* the elevation of temperature is most considerable and most continuous. A remarkable fact ascertained was, that there was no proportion between the elevation of the temperature and the excitement of the pulse. In *eruptive fevers* the rise of temperature was most marked in scarlatina, then in smallpox, and next in measles. In smallpox the temperature reached its maximum at the commencement of the eruption, then diminished, but again rises at the period of the suppurative fever. The temperature continued at a higher than in any known disease. In measles the heat is greatest at the outset of the eruption, after which it gradually subsides. In diseases of the *respiratory organs* the temperature rose in proportion as the parenchyma of the lungs became involved. In this disease there is always a correspondence between the temperature, pulse, and respiration. In acute phthisis the temperature was augmented, but in chronic it remained natural. In *anæmia* and *rachitis* the temperature is normal. In *anæmia neonatorum* it is below the natural standard. These observations are of value in the diagnosis of infantile disease. Thus, typhus fever is the only infantile disease in which a greatly elevated temperature is associated with a moderate range of pulse, and it may be diagnosed to a certainty in a child when the temperature is 40° Cent. or upwards, and the pulse at the same time under 100.

Variations.—Mr. Isaac Brown has recently recommended the use of distilled vinegar in drachm doses in the treatment of this disease. Independently of the beneficial effects attributed to it during the progress of the disease, this medicine is supposed to prevent the subsequent anasarca, as he states that since he has adopted the specified plan he never met with an instance of this sequel. Similar testimony is also afforded by Mr. Hunter, of Margate.

Impacted Fractures of the Neck of the Humerus.—Dr. Robt. Smith, in his work "On Fractures in the Vicinity of Joints," says, in reference to the diagnostic signs of this accident, they are remarkably obscure, and the true nature of the injury is exceedingly liable to escape detection: there is but little deviation from the natural form of the shoulder, nor is there any appreciable alteration in the length of the limb. When the surgeon places one hand upon the shoulder, and with the other rotates the elbow, the head of the bone will be felt moving with the shaft; no satisfactory information is obtained by examining the axilla, for, although perhaps a slight laxity may be felt near the junction of the humerus with the head of the bone, it is usually so inconsiderable that it cannot be looked upon as affording positive evidence of the existence of a fracture in this situation. In order, however, to form a more decided opinion as to the nature of the lesion which the bone has suffered, let the surgeon, with both hands, grasp the head of the bone with firmness sufficient to maintain it as nearly as possible in a fixed position, while an assistant rotates the elbow; by this method crepitus can be produced in the great majority of cases. The diagnosis of the *intra-capsular* impacted fracture is simple compared with that of the *extra-capsular* variety. The arm is slightly shortened, the acromion process projects more than natural, and the shoulder has lost to a certain extent its rounded form; the upper extremity of the shaft of the humerus is approximated to the acromion, and the entire of the globular head cannot be felt. In consequence of the fracture of the tuberosity, crepitus can be readily detected when the shoulder is grasped with moderate firmness and the arm rotated. Both forms of impacted fracture unite by bone. It is sufficient in the treatment of such cases to bandage the arm to the side, and to support the forearm in a sling. There will always be a certain degree of impairment of the motions of the joint.

Tubercles in the Lungs.—Dr. William Addison states, in their early condition, they escape notice, unless searched for with a lens in very thin sections, gently extended upon a dark background. To make out correctly the primary situation of a tubercle, the examination should be made in the lungs of young persons who have died of other diseases. The material deposited in the air-cells in *pneumonia*, and that forming a tubercle, has only the difference that exists between recently excreted and old pus. The same class of objects—incoherent colourless cells, molecules, and granular matter—appears to constitute the material in both cases; and in both cases, also, the material takes primarily the shape of the air-cells in which it is seated. In the material forming the consolidation resulting from inflammation, incoherent cellular forms predominate, as they do in recent pus; whereas, in tuberculous matter, granular masses and molecules greatly predominate, as is also the case in old pus. And, were we to imagine the fluid element of old pus removed or absorbed, the remaining solid matter would be tuberculous matter; the colourless elements of blood, pus, and tubercle, passing into each other.

Prognosis of Scurvy.—Professor Andral says that nothing is more difficult than the definite cure of those diseases in which the blood is robbed in a slow and spontaneous manner, either of its globules or its fibrine. It scurvy arises from evident external causes, it generally lides readily when those influences no longer exist; but if it comes on spontaneously, it will generally resist every possible means we may employ. In some cases, although the symptoms improve very greatly at intervals, they entirely disappear, and, after gradually increasing, finally terminate fatally.

Accidental Ossification.—The abnormal growth and development of bone, Mr. Hassall, in his *Microscopic Anatomy*, states, is a very common pathological occurrence. It is not, however, every ossific deposit which presents all the characters of bone: thus, those contained in the

ovaries, in the mesenteric gland, and in the coats of arteries, usually want the more conspicuous elements of bone—the bone-cells and lamellae—although these have been met with in ossific depositions remote from all connection with bone. In the repair of fractures we have a development of true bone preceded by the formation of cartilage.

On the Teeth. consists of phosphate of lime mixed up with the mucus of the mouth and epithelial scales: it contains also occasionally animalcules and vegetable growths, which find in the animal matter of the tartar a convenient nidus for their development. The accumulation of tartar around the necks of the teeth results from an opposite condition of the saliva to that to which chemists ascribe dental caries, viz., an alkaline state of it.

Fungi in the Mouth and Intestinal Canal.—In his observations on the microscopic characters of the aphthae of children, and of adults during typhus, Remak found that a single aphtha often contained several species of fungi, and that the species of fungi, occurring in different aphthae on the same individual, exhibited no constant relationship; also, that while one aphtha contained numerous fungi, others on the same individual contained none at all. Hence it appears that the loosening and ulceration of the mucous membrane is the primary phenomenon, and that the fungi are only produced under favourable chemical conditions. It has been long known that the presence of aphthae is usually associated with an excess of acidity in the primæ viæ; and it is very probable that a putrid condition of the surface of the mucous membrane would accelerate the conversion of sugar and starch into lactic acid, and thus afford a favourable soil for the growth of these fungi.

Spermatorrhœa.—Gonorrhœa undoubtedly predisposes to this disease, as was shown by Lallemand. But whether it be the gonorrhœa itself or the balsam of copaiba taken to cure it that causes this predisposition, it is difficult to say. The latter is probable, since it has been noticed by Schonbein to induce baneful effects on many persons who have taken it for gonorrhœa in full doses, and for a long time, giving rise to Bright's disease.

REVIEWS.

The Preservation of Infants in Delivery, being an Exposition of the Chief Cause of Mortality in Stillborn Children. By RICHARD KING, M.D., &c. London: John Churchill, 1847. Pp. 61. It requires no small share of physical courage, as well as mental endowments, to explore successfully one of the regions of science where philosophers who have gone before have been bewildered, and where there are but few waymarks to direct the traveller in his course. In his progress he must expect to meet with difficulties, and to surmount these he must use discreetly that knowledge which has been gained by experience. If under those circumstances all is not attained which was contemplated in the beginning, it may prepare the way for others who may be ultimately successful.

The author of the present essay has taken up a subject which possesses much interest in a physiological point of view, and one which in its consideration he can derive but little assistance from the labours of others. It is evident that he has had opportunities of making himself acquainted with the subject on which he writes, and that he has carefully observed those phenomena which he attempts to elucidate. His monograph is, therefore, entitled to the respectful consideration of his professional brethren, and, though they may have different views to those which he entertains, they must give him credit for a very plausible theory.

The question which he proposes to solve is, what is the chief cause of mortality in stillborn children? He had noticed that the number was considerable, and that many of them were

amongst the strongest and finest with regard to development; and, the question being answered, he proposes for adoption a practice which he thinks will save a large amount of infant life.

Dr. K. entertains the opinion, that the legitimate position of the afterbirth is against the walls of the uterus, and as far as his own researches extend they are in favour of the anterior wall. Moreover, he considers that there is uniformity in detachment of the afterbirth in natural and preternatural deliveries, which will help to explain why footlings should more frequently be stillborn than children of breech presentation, and the latter than those of natural birth; and he says that the duration of life in these several presentations is in exact proportion to the amount of time the uterus has sustained compared with the time which elapses from the supposed period of the detachment of the afterbirth to the birth of the infant. While, therefore, distinguished accoucheurs have troubled themselves greatly about pressure on the umbilical cord, which they think nearly always produces fatal results to the infant, our author holds that this is of rare occurrence, and that the theory of suffocation from pressure is altogether unfounded and unphilosophical, death more frequently arising from syncope from want of compression—the placenta "acting as a moist sponge released from the hand becoming gorged with blood at the expense of the infant." In presentations of the afterbirth he recommends its removal before the extraction of the infant, and that the placenta should be squeezed firmly in the palm of the hand, and not released until the umbilical cord is thoroughly compressed, lest it should produce a fatal syncope by absorbing the blood of the child. "The delivery of the afterbirth also," he observes, "before the infant must facilitate delivery, for to the loss of the placenta there would be a proportionate amount of contraction of the uterus, consequently a considerable gain of expulsive power; and, at my views are sound, by compressing the umbilical cord there would be a gain in time, and the probability of saving boys as well as girls." In the Cæsarean operation he thinks that the great object should be to secure the funis as speedily as possible.

For our own part we believe there is a great deal of truth in the author's statements, and they are worthy of the consideration of the practitioners in midwifery.

Thoughts on the Nature and Treatment of several Severe Diseases of the Human Body. By EDWARD J. SEYMOUR, M.D. Vol. 1, pp. 266. 8vo. London, 1847.

A physician of Dr. Seymour's experience, and habits of close observation, would naturally be expected to write something worth reading upon any practical subject which had commanded a good share of his attention. This is an *a priori* proposition which we should feel almost warranted to make before proceeding *de facto* to analyze his book. Indeed we did make it in our own mind, and, after having put the proposition to proof, have found that it was not idly made. The volume before us abounds in those useful hints and reflections which are alone the suggestions of vast clinical opportunities. Dr. Seymour has long enjoyed ample scope for the exercise of his skill and judgment as a physician, and we are happy to see that he has devoted himself to the task of giving, with no sparing hand, his copious gleanings to those of his professional brethren who have been less favoured in their calling.

The present volume consists of cursory observations, illustrated with cases, on diseases of the stomach, gut, mental derangement, and scintia.

These several subjects are not treated of in any specified or set manner, but what is said of each consists merely of a current of experimental observation, just such as a curious and cumulative mind would put forth. This makes the tone of communication easy, and the temper of it natural, practical, and truthful. What we say is well illustrated in the following passage concerning perforation of the stomach:—

"I was called, two years ago, to see a servant of all-work, about twenty years of age, who was dying with the symptoms of perforation. She had long complained of pain in the stomach; but went about her usual laborious occupations. Suddenly, after eating a very large meal of salted beef, she exclaimed, placing her hand on the region of the stomach, that she was shot! Violent vomiting ensued without much of the contents of the stomach being brought up. She became insensible, though still giving signs of pain when pressed with the hand upon the epigastrium. She died in about five hours after the attack. In the morning of that day she had appeared to be perfectly well.

"But it has been said that, even after perforation of the stomach, it by no means necessarily happens that the patient immediately dies. In two cases which occurred to me in St. George's Hospital, one survived the perforation five months, and another twelve days, after the most violent symptoms of peritoneal inflammation. As such cases are undoubtedly rare, i.e., cases in which persons have lived after perforation of the stomach, the secondary process which prevented immediate death has never been described."

The two cases are then subjoined, and excellently illustrate what adhesive inflammation is capable of doing to repair solution of continuity. In one case, "the left lobe of the liver, being enlarged, covered the greater part of the anterior surface of the stomach. On lifting up this portion of the liver, the contents of the stomach oozed out of a small aperture, which was partly blocked up by adhesions between the two organs. Another small ulcer was found at the lower part of the posterior wall (of the stomach). This ulcer had merely destroyed the mucous membrane, the margins of which were firmly united to the subjacent parts."

In the second case, "on the posterior surface of the stomach, towards the great curvature, was a large ulcer, which had completely destroyed the different coats, the deficiency of which was made up by the pancreas adhering to the circumference of the ulcer: the edges of the ulcer were levelled off, and perfectly smooth. The surface of the pancreas, which thus formed a part of the stomach, still retained its granular appearance; but it was covered over by a thin smooth membrane."—(Pp. 18—25.)

The chapters on the other subjects, especially that on gout, which is the longest, and not the least important, of the whole, are made up of the substantial practical material which has pervaded the quotation we have just given. Occasionally, Mr. Seymour throws in a reference, an illustration from a fresh source, or an anecdote, which serves to enliven and enlighten the otherwise somewhat dull continuity of invariable detail and practical reflection.

The style of our author is for the most part clear and simple, and not seldom eloquent; occasionally, however, the phraseology is loose, and in places inaccurate. This is plainly the result of inattention—but it could be better corrected—such a fault is a growing one.

Altogether, we like the book excellently well, and we gladly commend it to the notice of the medical practitioner.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

Discipulus has been misled by his advisers. He has only to use discretion, and retract his footsteps. Agonistes must permit us to publish his name, or to have it in confidence, or otherwise we could not allow the long statement which he makes to appear.

Mr. Roache's letter can only be admitted as an advertisement. Our correspondent asks a considerable favour.

Truth-seeker informs us that he was once inclined to believe in the homoeopathic theories, but he has found that it is strict attention to a patient's diet that accomplishes all the good which is erroneously attributed to infinitesimal doses of medicine.

Mr. Blachley may consult with advantage John Hunter's celebrated works. Bad surgeons, he says, are like bad carpenters: they make work for each other.

A Member of the College may easily discover the names of those examiners who signed Mr. Blake's diploma. We have heard nothing of the brassy statue which it is proposed to erect to his honour.

Mr. T. Neal shall hear from us privately.

A Liverpool Reformer is thanked for his information.

Scottus.—The faculty of Physicians and Surgeons of Glasgow had a narrow escape of strangulation during Sir James Graham's Secretaryship. They still dread a speedy dissolution thence they hail with satisfaction the Wakley Registration Bill, as it will avert from them impending danger.

Magister.—The apprentice must serve his time, or the indentures may be retained; without these he has no chance of getting the license to practise.

Mr. Beazant.—The Polytechnic Institution.

Chirurgus.—The treatment of aneurism by compression is not new; the pressure was sometimes applied to the sac, or to that and the artery leading to it. It is said that an Italian surgeon was the first who thought this disease might be cured by pressure.

Amicus, Bristol.—Hippocrates had some knowledge of placental presentations, and he thought that if the afterbirth came first the child could not live.

Mr. William Smith, Belper.—The communication has been received, and will be inserted in an early number.

A Subscriber, Boston.—"Guy's Medical Jurisprudence."

Dr. Tyler, Harcourt-street, Dublin, is thanked for his interesting paper.

W. G.—The suggestion will be attended to.

Mr. J. Thomas, Carlisle.—There is some doubt about the matter.

M. S. Bristol.—We cannot assign a cause; it would be best to consult some medical gentleman in the neighbourhood.

Mr. Geo. Turner, M.R.C.S.—Quest. 1. Consult the University Lists. 2. No. 3. Doctor by courtesy, not by right. 4. No. If in the country, there will be some difficulty in getting access to the authors mentioned, unless their works are purchased.

Chirurgus.—We are sorry that there has been so much disappointment in reference to "Dr. Quain's Anatomy," and we hope, as our correspondent says, "that literary gestation will soon be complete, and the author safely delivered."

Medicus, Dublin.—We think not.

A. W. C. writes to us as follows:—"Can you tell me how to separate the line of bone from the gelatine, &c.? This question might be satisfactorily answered, but with the following stipulation I cannot reply to it:—I want the earthy matter, as well as the other, separate and distinct, yet unaffected by the process. Perhaps some of your correspondents will favour the inquirer with some information which may tend to elucidate the matter."

A Constant Reader, Elgin, N. B.—The fault is not with us that the Medical Times is not received as soon as it ought. It is always published early on Friday, and might, of course, be posted on the same day.

J. B. Hackney.—There are many who were at first misled, but have since thought proper to change their opinion as to the advantages which the Registration Bill will confer on the profession. Of course their defection will be passed over "in solemn silence" by the Finsbury member.

A Pupil's objection to the Registration Bill—"that, if passed, it would depress the social status of medical men fifty per cent."—is well founded. It would be idle, in any such deplorable event, to talk of the word "gentlemen."

M. B. H. would oblige us by forwarding to us the

response of his representation on the necessity of moving for the committee he suggested.

Novus Homo is inadmissible. He should convey his opinions to Mr. Bannerman, or to the organs which supposed "intrigues" he condemns.

Marous is thanked.

Mr. J. H. will find the article he inquires for in the last volume of the Medical Times.

Amicus thus addresses us:—"Your exertions in the Housfield case having won for the profession an extended recognition of their rights—and especially of the right not to be postponed as a witness to any pursuits or friend—you would add to the gratitude of the profession if you would form a society for the purpose of restoring any encroachment by coroners on the just privileges of medical witnesses." The suggestion is not unworthy of consideration.

M.R.C.S.I., Liverpool.—Not in England.

Mr. Burton, Ulverstone.—Received.

Incognitus had better use a little self-government. We know not to what communication he refers; if sent, it was either not received, or has been mislaid.

Inquirer "wishes to ask of Dr. Copland, the author, and Messrs. Longman and Co., the publishers, of it, when 'The Dictionary of Practical Medicine' will be completed." Inquirer complains of broken engagements, and the increased price of the work. He had better wait than seek assistance from the law.

Juvenis.—King's College Hospital. Mr. Dermott is an efficient teacher.

Qualification.—There is no remedy. The present medical gentleman being in office, the guardians can continue him as long as they please.

R. G. C., Kilrush.—A Scotch physician cannot practise in London legally without a license from the College of Physicians.

X. Y. Z.—The case had better be laid before the Apothecaries' Society, who will take up the case if there are good grounds.

Mr. Howard, Heaton.—"Brand's Chemistry."

Letters and communications have also been received from Mr. Beazant; Mr. Thomas Neal; Truth-seeker; Mr. Blachley; Discipulus; Agonistes; A Liverpool Reformer; Mr. Leonard Strand; A Member of the College; Scottus; Mr. Wm. Smith, Belper; Amicus, Bristol; A Subscriber, Boston; Mr. A. Tyler, Harcourt-street, Dublin; W. G.; M. S., Bristol; Mr. G. Turner, M.R.C.S.; J. B. Hackney; A Constant Reader, Elgin, N.B.; Chirurgus; Medicus, Dublin; A. W. C.; Mr. Barton, Ulverstone; Mr. Howard, Heaton; X. Y. Z.; R. G. C., Kilrush; Qualification; Juvenis; Inquirer; Incognitus; M.R.C.S.I., Liverpool.

Several lectures and communications which have been promised an early appearance must stand over to our next.

THE MEDICAL TIMES.

SATURDAY, JUNE 5, 1847.

PROFESSIONAL JEREMY DIDDLERS AND THEIR DESERTS.

In discussing the affairs of the medical profession we have been compelled on many occasions to severely censure the conduct of those corporate institutions which have the power of legislating for its members, and of admitting whom they please within the pale of their several establishments. Placed as they are at the head of the profession in this country, they cannot fail to exercise a powerful influence for good or evil; and it seems, from the present aspect of medical affairs—from the restlessness and dissatisfaction which are universally manifested, that the ruling powers have not been faithful to the trust committed to their charge.

Our position is in the business of the Gulf, and it is in fact
a complete identification with its economic influence.
There is no other power more effectively demon-
strated in this principle.

Under the plan, the Secretary of State is invested with arbitrary power over the course of the investigation of all claims of the Government. It is an isolated intention, nothing more. It is capricious, and, in association with the provisions, nothing could possibly be more arbitrary, perilous, and destructive to the interests of the general practitioners. The amended text of this clause I have already exhibited to you.

That is not a proper title to the clause. It is not a thing, and it is more twaddling than a child's toy. It is not the purity of the profession, as is implied by the language of the bill. It is not desirable that a power of punishing disgraceful conduct shall reside somewhere, but the body before whom the case is brought should be competent to decide upon its own merits, be discreditable or not. The judicial body will be competent to decide in all cases upon the immorality or indecency of an action without unduly prompting as appears in the proposed bill. The vague enumeration of offences is simply undignified and meddlesome verbiage.

For my own part, gentlemen, I believe that the standard of the profession can be elevated only by a high and strict educational discipline, and by the cultivation of friendly intercourse among the constituent members—and that the establishment of a new college will tend most directly to achieve. Flagrant offences require, however, positive punishments, it is therefore expedient that there should be suitable statutory enactments to meet such cases as violate the decencies which professional honour requires.

Sir James Graham proposed to destroy this exemplary body, and, with the sword hanging over their heads, they are ready to prostrate themselves before any individual whose hand promises to intercept the blow. It is instant, and no more worthy of blame than the bread-eating of a famishing man, I do not censure, neither can I praise, least of all can Mr Wakley shed, hear, subject for congratulation.

Again, gentlemen, what voluntary body has

authority than they themselves would dare to demand.

No council, gentlemen, should have the power to deprive, in a summary manner, any member of their college of his character and his bread. There should be an appeal from such decision. The attempt to ingraft this irresponsible power on the present intolerable jurisdiction of these councils is monstrous. Their sentence will be irrevocable, and the ruin of an individual will be complete. No attorney can be struck off the rolls unless he has been tried before the Court of Queen's Bench and the highest courts in the realm; and are we to have no appeal to a superior court?

Further, gentlemen, the powers proposed to be conferred on the Registrar are equally unconstitutional. He also can strike any name off the register, and his *fat is final*. Mr. Wakley seems resolved that an unfortunate member shall not escape; he seems to delight in persecuting a misdemeanant; he is either pertinaciously just, or atrociously unjust, as the case may be. Resolved that an offender shall not evade judgment, he is also resolved that he shall have no appeal. The exculpation of an innocent man is a matter of high disdain to him; although, probably, if this law had been in operation thirty years' since, Mr. Wakley might have spent the latter years of his life in unavailing repentance, and dishonoured destitution. I am not sure, if this bill should become law, that his own name would not be the first erased from the register. There are not wanting those who would say it was righteously done.

Such are the unconstitutional powers sought to be conferred by this bill. A professing Liberal is the ally of your oppressors. Scandalizing honesty of principle, and putting consistency to the blush, he is busy forging shackles for the men who have committed their liberties to his charge. His sympathies are with the despotic councils. He has himself declared that the powers I have denounced are unfair, and might be *misquotingly* employed! I hesitate, however, to quote him as an authority. I know not but that, next week, he may call me liar, and *pro* himself one.

Gentlemen, it is your bounden duty to rise in opposition against the bill. Your sluggishness will be your ruin. Have I argued truly,—placed the clauses of the bill in a just light before you, and drawn honest conclusions? If you think so you ought and must petition the House against the measure. *Do it at once*, it is of the utmost importance that you should act while the special committee are conducting their inquiry.

I do not expect to please all dispositions and remove all prejudices, there may be some who are still hard to convince; let such men read the bill again for themselves; and, unbiassed by my comments, which are addressed to a variety of interests, and which reflect, perhaps strongly, the impression of my own mind, dispassionately consider the more important clauses, and establish their judgment.

You may rely upon it, gentlemen, that the general practitioners can never be in a safe or honourable position until they are incorporated in one body; and the moment that they abandon this enterprise they lose all chance of acquiring their just rights. It is much easier of attainment than some of you imagine, and it requires only a persevering and united effort to accomplish its fulfilment.

I have learned that there are certain sneaking and underhand attempts now in progress to di-

vide the members of the Institute. Let such unmanly stratagems be treated with scorn.

I have the honour to be, Gentlemen,

Yours, very faithfully,

VOX VERITATIS.

THE SELECT MEDICAL COMMITTEE.

This committee consists of the following members:—

Mr. Macculay (chairman), Sir James Graham, Mr. G. Hamilton, Mr. Bannerman, Mr. Acland, Mr. Wakley, Mr. Hawes, Mr. Fitz-stephens French, Sir Robert Harry Inglis, Mr. Dennistoun, Viscount Sandon, Mr. Boyd, Mr. Aldam, and Mr. Lascelles.

Power to send for persons, papers, and records. Five to be the quorum.

The examinations will commence this day (Friday). The office-bearers of the College of Physicians will take precedence in the examinations. Monday will be given, it is expected, to the College of Surgeons, and successive days to the other institutions.

MISCELLANEOUS CORRESPONDENCE.

THE NATIONAL INSTITUTE OF MEDICINE, SURGERY, AND MIDWIFERY.

[To the Editor of the Medical Times.]

"4, Hanover square, June 2, 1847

"SIR,—I am requested by the committee of the National Institute to forward to you the enclosed, which you will oblige them by publishing.

"I am, Sir, your most obedient servant,
"GEORGE RONS, Secretary."

A document, of which the following is a copy was this day left at the offices of the National Institute, by three gentlemen with whom the clerk was unacquainted, and who did not give their names. Two notes were left at the same time, copies of which are also annexed. Neither the document nor the letters of withdrawal enable the committee of the National Institute to determine under what circumstances the signatures have been obtained, or whether the document emanates or not from a public meeting the committee are desirous that it should be published without loss of time, in the exact state in which it was received.

The committee forbear to offer any observations upon the document in question, although it has been evidently prepared in ignorance of the principles which have influenced the National Association as well as the National Institute throughout the whole of their proceedings.

[COPY, NO. 1.]

"Middleton-road, Dalston

"June 2, 1847.

"SIR,—The opposition of the Council of the National Institute to the Medical Registration Bill, now before Parliament, not being in accordance with my views upon the subject, I beg that my name be at once erased from the list of members.

"Your obedient servant,

"E. B. BOWMAN."

[COPY, NO. 2.]

"1, Queen's-road, Dalston

"June 2, 1847.

"SIR,—The opposition of the Council of the National Institute to the Medical Registration Bill, now before Parliament, not being in accordance with my views upon the subject, I beg that my name be at once erased from the list of members.

"Your obedient servant,

"J. DALSTON JONES."

[COPY, NO. 3.]

"TO THE COUNCIL OF THE NATIONAL INSTITUTE OF MEDICINE, SURGERY, AND MIDWIFERY.

"We, the undersigned members of the Nation-

Institute of Medicine, Surgery, and Midwifery, take upon us thus publicly to republish the address published by the Council of that body against the Medical Registration Bill, now before Parliament, having neither been asked nor consulted upon the merits or demerits of the measure; also to deny the right of the Council to issue an address of such paramount importance to all its members, without endeavouring to elicit their views upon the subject. If they possessed the means of knowing the individual opinion of the body for the election of the council, they surely possessed the same means for ascertaining their views upon a measure where they one and all were so deeply interested.

"Feeling that the Council had by its precipitancy pledged itself to oppose a measure, the success of which the members at large were most favourable to, we are anxious that the members of the Legislature, and more particularly the committee now sitting in the House of Commons, should know that the opposition of the Council of the National Institute is not that of its members.

ON THE USE OF OXIDE OF SILVER AS A REMEDIAL AGENT.

The use of oxide of silver as a remedial agent is daily increasing. I believe any facts in relation to the compounding of it that may come under the notice of the dispenser to be his duty to lay before the profession, for, like all other novelties in medicinal science, experience only can lead to beneficial results, and the want of experience is likely in all cases to lead, and with this substance must lead, to very pernicious results.

The usual form of administering it I believe to be in pills, containing about half a grain each; but if, in the preparation of these, the confectio roseæ gallica be used as a vehicle, it forms an explosive substance; and with this, like other similar substances, you cannot fix with any certainty the period of its explosion, so that, should it not explode before taken, the party taking it will be swallowing a substance almost certain to explode with the heat of the stomach.

It also forms an explosive substance when combined with an essential oil—a combination many physicians are very fond of, but a most dangerous one.

It, therefore, now becomes a subject worthy of the attention of the chemist, pharmacist, and physician, what substance it can be combined with in safety. The examination of all these its requires an immense deal of labour, and but repeated experiments can lead to all results; but a subject of such importance surely must not be passed over on account of the labour attending its investigation.

I must beg pardon when for a moment I would depart from the rules of philosophic research, and throw out one or two theories upon this substance, which I employ to put the physician or practitioner upon his guard.

I believe the explosion to result from the slight affinity which he has the carbon and hydrogen together in both sugar and essential oils, in

of which substances it is in large quantities.

I consequently believe the same results would follow its combination with starch, all saccharine matters, and all bodies where carbon and hydrogen are present in large quantities, and where their component parts are held together by a very slight affinity for each other.

Seeing the majority of extracts contain a large quantity of either starch or saccharine matters, care should be taken how we combine it with them.

With these remarks I would conclude, leaving the subject open to the investigation of all, though I trust soon to be able to offer you a few more remarks upon its action.

J. UNDERWOOD.

4, Grafton-place, Kentish-town.

P.S.—I noticed the effect of the conserve while preparing some pills with it at 199, Fleet-street; and the effect of the oil was noticed at Messrs. Allen's, Plough-street.

A WHOLE FAMILY POISONED.

On the evening of Sunday last there occurred, at Kensal-green, a more painful accident by poisoning than we ever remember to have heard of on any preceding occasion, the result of which is that six persons have been killed, and three others are in imminent danger. A man named Thomas Hickman, aged thirty-four, occupied, with his wife and six children, a small cottage in Penton-villas, Middle-row, adjacent to the cemetery at Kensal-green. On Sunday morning last Caroline Boneroy, a sister of Mrs. Hickman, called to spend the day with her relatives, and during the morning she was asked by her sister, who was otherwise engaged, to prepare a rhubarb-pudding for dinner. It appeared that after the batter was mixed, and all the flour exhausted, the substance was too thin, and on going to an adjoining cupboard she found in a paper bag what she imagined to be another package of flour. This she added to the former mixture, and the whole was sent to the bake-house. At dinner the family, including the sister of Mrs. Hickman, partook heartily of the pudding, little suspecting that it contained a deadly poison. Shortly after they had partaken of the pudding, very alarming symptoms were perceptible in the whole of the children. They were first seized with violent sickness, accompanied by a burning sensation in the throat and stomach. Whilst Mr. and Mrs. Hickman were attending upon their offspring, they were, together with Caroline Boneroy, attacked in a similar manner, and they then for the first time imagined that the fruit in the pudding had caused the symptoms, and assistance was called in.

Mr. Abercrombie, a surgeon, of the Kensal-road, was promptly in attendance, and, seeing the state the parties were in, he inquired what they had eaten? He was told a quantity of rhubarb-pudding, and was shown the remainder of it, which was lying on the table. From the symptoms which showed themselves, he was positive that it was not the fruit in the pudding, but some violent poison that was acting on their constitution; and, from the metallic taste they described as having in their throats, he felt convinced that they had partaken of arsenic. He made known his suspicions to the sufferers, when Mrs. Hickman's sister exclaimed, "It must be that white composition which I found in a bag in the cupboard, and which I mixed with the pudding." Hickman, on hearing that, exclaimed, "My good God! why, that is the white arsenic I have had in the house so many years!" Mr. Abercrombie immediately on hearing this administered the usual antidotes, and did all that the nature of the case would admit of, but without any beneficial result; and at six o'clock James Hickman, a fine youth only nine years of age, died from the effects of the poison. In the course of an hour and a half afterwards another of the children, named John, three years of age, also expired. A third child, aged eighteen

months, named Henry, next died. Mary Ann, aged four years and a half, also died at half-past ten. At eleven o'clock on Sunday night, the fifth child, named Harriett Elizabeth, aged six years, expired. Mr. Abercrombie continued in attendance throughout the whole of Sunday night and Monday morning; but, in spite of all his efforts, the father of the above unfortunate children died at half-past twelve on Monday. He was only thirty-four years of age; and at the time of his death he exhibited the greatest anxiety for the fate of his wife and offspring.

Mrs. Hickman, her sister, and her son Thomas, aged twelve years, are now (Wednesday) still alive, but their ultimate recovery is doubtful. Mr. Abercrombie has taken possession of the remainder of the pudding, and what they had thrown off their stomachs. The latter he has analysed, and found that it contained a considerable quantity of arsenic, and, on questioning Caroline Boneroy, he learned from her that the bag contained at least half a pound of that poison.

The statement made by the husband prior to death, and which was confirmed by his wife, was, that a quantity of arsenic had been kept in a bottle, but some time since, by mishap, the bottle was knocked down and broken, and the contents were afterwards placed in an old flour-bag, and deposited in one corner of the cupboard, where it remained until removed by his sister-in-law.

In explanation of the large quantity of arsenic so carelessly placed in a cupboard, it may be mentioned that the deceased Hickman had formerly been a glassblower, in which capacity he had frequent occasion for the use of the poisonous substance. Nothing, however, can be offered as a sufficient excuse for the carelessness of leaving so large a quantity of so deadly a poison in a cupboard amongst articles of food, and, above all things, in a flour-bag. Rumours have been afloat to the effect that Hickman intentionally poisoned himself and family. There can be no doubt, however, that this statement is incorrect. A coroner's jury was convened for eleven o'clock on Tuesday, but the inquest was adjourned.

CHARGE OF POISONING AGAINST A CHILD.

At Southwark Police Court, on Monday, Henry Asher Fitzjames, a boy between eleven and twelve years of age, was charged before Mr. Cottingham with attempting to poison his mother and her infant, the latter three months old.

Mr. Cottingham, on being informed that there was no person in attendance to press the charge, remarked that the accusation was one of such an extraordinary and serious character that he felt bound to investigate the affair. He then called upon the policeman to state the circumstances under which the boy was given into custody; and his account was, that the mother brought her son to the station-house the preceding day, and said that he had mixed poison with the water she had used that morning for her breakfast, and from the effects of which she was then suffering. She also said that he had attempted on former occasions to poison her, and that her infant, three months old, was then lying in a hopeless condition, owing to the boy having mixed up small pieces of broken glass and precipitate powder in its food; that upon hearing the nature of the charge it was immediately reduced to writing on the police sheet, and the accused, who did not deny it, but continually beseeched forgiveness, was then looked up. The mother was directed to be in attendance to proceed with the complaint that morning, but instead of doing so she absented herself, and he (the policeman) believed that it was not her intention to come forward.

Mr. Cottingham then sent a policeman for the prisoner's mother, and after some delay she attended, but evinced a strong repugnance to proceed with the charge against her child, until the magistrate impressed upon her the necessity

of it, as well for her own sake as for that of the rest of her children, and also on the part of the public, for there was no knowing what mischief had of such an atrocious spirit might do it suffered to go unchecked in his career.

The mother, who gave her name Anne Fitzjames, said that she was the wife of a traveller now abroad, and that she lived in Ilmow-place, Millpond-bridge, Rotherhithe, that on Sunday morning she had coffee for breakfast, and about half an hour after partaking of it she was attacked with violent pains in the stomach and a disposition to vomit which she encouraged by taking copious draughts of hot water and brought away the contents of her stomach, when she became better. She afterwards made some inquiries about the coffee of her daughter, a little girl, and from her she heard that her son the boy at the bar, had thrown a quantity of precipitate powder into the pot which contained the water with which she had made the coffee in breakfast. She added that she had not told falsehoods, and that she had contradicted herself in the matter.

Inspector Hornsby here informed the magistrate that Mrs. Fitzjames, when at the station-house the previous day, informed him that it was not the first attempt the boy had made to poison her, that he also attempted to poison the person to whom he was apprenticed, and, in fact, she said many more things tending to eliminate the boy which she now seemed unwilling to disclose.

Mr. Cottingham (to the mother). Is it true your son attempted to poison you on a previous occasion? I have already cautioned you as to the importance of investigating this dreadful charge to the utmost, and you are, therefore, bound to tell me all and everything that has reference to it, in order that the truth may be elicited. Has the boy made a similar attempt before?

Mrs. Fitzjames replied that about ten months ago she was taken suddenly ill, and that her daughter then told her that her brother had mixed arsenic in some tea which she drank.

Mr. Cottingham. Can you tell the reason he attempted such a wicked act? Had you chastised him or given him any cause to be provoked with you?—Mrs. Fitzjames. None that I am aware of, he has certainly been a bad boy, and had on different occasions taken money and other property from me.

Inspector Hornsby said that on the preceding day Mrs. Fitzjames told him that the boy administered the poison to her in order to get possession of her goods and other property.

Mr. Cottingham here remarked that he was sorry to perceive that Mrs. Fitzjames still manifested a disinclination to repeat the whole of the circumstances, he would make allowance for a mother's feelings, but still he must be put in possession of all the facts bearing upon the case. The magistrate then directed that Inspector Hornsby should repeat all that Mrs. Fitzjames said to him on the subject of this charge at the station house in the presence of her son.

The inspector was then sworn, and he said that Mrs. Fitzjames, when giving the boy into custody, described the circumstances attending his mixing precipitate powder in the water with which she had made the coffee, and also of his having upon a former occasion put arsenic into her food, and that when the boy was questioned by her as to his motive for doing it he replied that a man named Jones had said to her, advised her to do it, in order to get possession of her property, telling him that if he killed his mother they would divide all belonging to her between them. The inspector added, that the mother also mentioned to him that the boy had attempted to poison his sister, and also said that his infant, three months old, was now dying from precipitate powder which he had given him which the boy had mixed in his food.

Mr. Cottingham inquired whether the prisoner repeated his mother's statement at the station-house? The reply was in the negative, that the

only words the boy uttered were, "Mother, do pray forgive me."

The mother was here interrogated by the magistrate and in reply to his questions she said, that the inspector's statement of what took place at the station-house was perfectly correct. She added, that about five weeks ago she detected a powder resembling arsenic in the water she was about to use; but she did not take the water to chemist to have it analyzed, under the apprehension that it would get the boy in trouble and it being such a dreadful thing for a mother to accuse her son of an attempt to poison her. On that occasion, when she questioned the boy, he admitted that he had mixed arsenic in the water, adding that Jones gave it to him, telling him that if his mother swallowed it it would kill her and that then he would have all her money. She added, that on that occasion she was exceedingly ill, having drunk a small portion of the water that she went to bed in the morning, but did not decide to have her application for a doctor, as she thought she was not so ill as she felt. She never saw the man Jones.

Mr. Cottingham. Had you or the boy's father ever told him that he was likely to be put to death if he was convicted?—Mr. Fitzjames. I told him nothing of the kind, we were cautioned by either of them.

Mr. Cottingham then, addressing the prisoner, who cried during the latter portion of the examination, asked him what he had to say in answer to the charge?—Prisoner. I said a great deal that was untrue to get myself off when my mother took me to the station. I thought that I said that I gave her poison in the coffee, but I never put a particle of precipitate powder in the coffee or the water.

Mr. Cottingham then why did you tell your mother's story when she was repeating what you had previously told her at the station house?—Prisoner. Because she threatened me with the police. I know Jones. He wanted me to give my mother poison to kill her to get her property, but I told him I would not.

Mr. Cottingham. How long have you known Jones?—Prisoner. Since Christmas. I met him in the Borough market after I run away from my master, and he wanted to take my boots and my cap. I told him where my mother lived, and all about my running away, and by his advice I went to sleep at a workhouse, and told the porter that I belonged to Liverpool. The next time I saw Jones he proposed that I should kill my mother, and said that he had poison to give me to do it. He showed me a powder, saying it was arsenic, but I refused to accept of it.

Mr. Cottingham. Have you seen Jones lately?—Prisoner. No, I have not.

Mr. Cottingham: You told your mother about putting broken glass and precipitate powder in the child's food, is that true?—Prisoner. I did tell my mother so, but it is not true, I never did anything of the kind.

In reply to Mr. Cottingham, Mrs. Fitzjames said that she threw away the coffee grounds, that she kept no precipitate powder, arsenic, or anything else of a poisonous nature in her house, that she remembered several months ago sending out the prisoner for a pennyworth of precipitate powder, the greater part of which was used for her children's hands, but she did not know where he purchased it. Her infant was very bad that morning and not expected to live. She had not mentioned to the doctor who attended the child about the precipitate powder or glass suspected to have caused its illness, under the fear of the consequences to her other child (the prisoner).

Mr. Cottingham said that it was really dreadful to contemplate a lad of the prisoner's tender years attempting not only to destroy his own mother, but also her infant, by means of poison. The case at present was involved in mystery, but he must say that he did not believe one word of the boy's assertion with regard to his having been advised by a man named Jones to poison his own mother in order to obtain possession of her property. Thus the (the magis-

trate) refused to release the prisoner from his custody without a charge. He, however, would investigate the case thoroughly, and would give directions that the prisoner be placed in a part of the county gaol or removed where he would have no opportunity of having intercourse with any of the other prisoners; and that he should also request the chaplain's particular attention to be directed to the prisoner, with the view of impressing upon his mind the situation in which he was placed, and obtaining from him such information on the subject as would lead to a full disclosure of the whole of the circumstances, and also of ascertaining whether the boy was the originator of the atrocious attempt upon his mother's life, or whether he had been goaded on by some villain whom he met with at the time he absconded from his master. At all events, the most rigorous inquiry should take place into a serious matter. The magistrate then remanded the prisoner for a week, desiring that the police should use the most active exertions to discover whether he had purchased any arsenic or precipitate powder in the neighbourhood, and he also requested Mrs. Fitzjames to call in the aid of a medical man to her infant, and in the event of the death to have a post mortem examination, with a view to discover whether ground glass and precipitate powder had been administered in its food.

The prisoner sobbed aloud on hearing that he was going to be sent to prison, and was then removed from the bar.

MELANCHOLY SUICIDE.—On Sunday week Dr. Alchemus, the physician to the Bedford General Infirmary, committed suicide by taking poison and in the committee-room of the institution. The deceased had been at the infirmary all the morning, and had been seen by a number of persons throughout the day, but he appeared in his usual health and spirits, and had not betrayed anything in his manner likely to attract particular attention or suspicion. He has left a wife and six children to bewail his untimely loss.

On Wednesday, the 2nd inst., the St. Pancras Board of Directors concluded an inquiry, which had been pending for three weeks previously, respecting the conduct of Mr. Thomas Henry Cooper, surgeon to the workhouse of this parish, in reference to the case of Sarah Naden, a young girl sixteen years of age, who, on the morning of April 20, gave birth to a stillborn child in the infirmary of the workhouse. The labour was stated to have been natural, but the removal of the placenta did not follow for several hours. Mr. Cooper, who was present, was requested to administer ergot of rye, but he decamped, and finally removed the placenta twelve hours after delivery. A few days after, the patient died of puerperal fever. Several members of the board having become acquainted with the history of the case, Mr. Cooper was called upon for explanation, which not being satisfactory, the case was referred to Dr. John Hull Davis, physician to the Royal Maternity Charity, whose report was on Wednesday read, in which he gave his opinion that the surgeon, knowing, as he must have done, that the practice and opinions of the present day were against him, had done wrong in allowing the placenta to remain. After a very full investigation, and some resistance from Mr. Cooper, the following motion was carried without a dissentient voice:—"This board, having been repeatedly called on to express its censure at the general conduct of Mr. Cooper as its medical officer, feels itself under the painful necessity of recommending to the vestry the removal of Mr. Cooper from his present office."—"Our readers will recollect that Cooper is the person who, with (one, or it may be two) other agitators, formed Wakley's successive mock-associations, the other moiety figured the other day in the newspaper reports of the Bankruptcy Court.

Dr. Wagner, the celebrated professor of Berlin University, has just died in the fifty-fifth year of his age.

SUGGESTIONS

FOR A MORE SIMPLE ARRANGEMENT OF THE

MATERIA MEDICA,

BASED ON ITS PHARMACEUTICAL AND THERAPEUTICAL RELATIONS.

By GEORGE LEITH ROUPELL, M.D.

Cantab., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Bartholomew's Hospital, Lecturer on Materia Medica at the College of St. Bartholomew's Hospital.

LECTURE I.

The numerous classifications of the materia medica which have been suggested at different times, and the objections which may be urged against all, will justify a further attempt at arranging this extensive and complicated subject. It is well known that this is the most distasteful of the various pursuits to which the mind of the medical student is directed. That such should be the case appears strange, when we reflect that its object is the history of certain agents possessing the singular power of influencing the system, so as to control morbid actions, and thus to cure disease. How, it may be asked, can topics such as these be viewed with indifference or apathy, or what reason can be assigned for the repugnance often exhibited towards them? Phenomena more interesting cannot be pointed out in the physical world, nor can incidents more gratifying be disclosed by physiology. No one will deny, moreover, that an accurate knowledge of materia medica is necessary in practice. Many have deeply regretted their neglect of this department of their studies when their acquirements have been tested by examination, and when afterwards they have been called upon extemporaneously to prescribe.

The claims, then, of this subject to attention are sufficiently obvious. Equally clear also is the fact, that it often fails to command the thoughts of the pupil. It becomes, therefore, of moment to inquire into the reason for the slight so often exhibited towards it, and the slender amount of knowledge respecting it with which the young practitioner commences too frequently his career. The reasons for this I believe to be the great extent of the subjects included under the term "materia medica," and the general want of connection in the arrangements of them usually adopted. These appear to me the chief drawbacks to the willing pursuit of this study. It is to be apprehended that pupils when commencing it have felt as if entering into an interminable labyrinth, and been, as it were, lost in the confusion which the numerous collateral sciences may readily be supposed to create in minds previously untutored, yet at once directed to them all. Should this be so, or, further, should the feeling of inability to master the task set before the student impress itself upon him, should the idea enter his imagination that the endeavour to tax his memory with what is laid down as essential to be

known were hopeless, then would materia medica, or any other pursuit, be turned from with aversion, and naturally abandoned in despair. It may be that doubts have arisen with some, and that early in their pupilage, of the real necessity for the whole phalanx of remedial agents which is to be seen upon our shelves. Quaint sayings are current of men eminent in our profession who have contrasted with marked antithesis the number of diseases which at the close of life they found to be irremediable, with the host of certain cures for every disorder with which they believed themselves furnished at its commencement. The declarations, too, of certain successful practitioners, that they did not use a dozen of the many simples and compounds with which our "Pharmacopœias" are enriched, may have had the influence with many. One distinguished for the clearness of his views and his just appreciation of symptoms has declared that he wants no other tools to work with than calomel, jalap, bark, and opium. Doubtless, the thorough knowledge of a few active remedies is all that can be required for the energetic treatment of acute, simple, uncomplicated disease. This, however, is by no means what we meet with in ordinary every-day practice; and were the attempt made to enforce such simplicity, let our agents be as powerful as they might, it would utterly and entirely fail. As easy would it be to restore to society the primitive manners of the desert, or to make all mankind think and act alike, as it would be to restrict the practitioners of medicine to the exclusive use of a few chosen drugs. Granting, then, the necessity for retaining, if only for the sake of variety, a long catalogue of medicinal agents, under the head of the materia medica, the question naturally arises of how these are to be arranged? Can any classification be suggested freer from objection than those now chiefly employed? Before entering, however, into this inquiry, it is not irrelevant that we should be reminded of the broad steps by which the present knowledge of the materia medica has been attained, and of the position which it may be said to occupy at this time. The first step of all would, of course, have been the discovery of the simple fact that certain substances possessed active medicinal properties. The next would be the employment of them in the cure of disease. The third step would be the acquirement of skill in the use of remedies, so as to adopt the appropriate ones to particular disorders. A fourth step has been made, and that

is, the inquiry into the composition of the organic substances which constitute the materia medica. They have, in almost all instances, been investigated analytically, and their components separated in a purer form. It cannot be necessary to dwell upon the importance of ascertaining the active principle of drugs. Upon this knowledge depends our estimate of the absolute or relative value of different samples; by it we direct the preparation or regulate the admixture of our compounds. This knowledge, too, enables us to exhibit our remedies when desirable in a small compass and in a concentrated state. Great strides have thus been made in the progress of the materia medica. Much has been accomplished pharmaceutically, but it yet remains for physiology and chemistry united to unfold to us the secret workings of a large portion of our medicinal agents. We are yet much in the dark as to the processes by which restoration from sickness to health takes place. We may, however, consider certain data as established:—

1. That the cure of disease is effected as the nutrition of the body is performed, through the instrumentality, namely, of various organic and other principles.

2. That these agents operate by the manner in which they modify, directly or indirectly, the morbid actions of the system.

We have, then, in looking at our list of remedies, to think of the chief principles which they contain—to find out that in our medicaments which has the power of acting, to ascertain its nature, and then to measure its power. In very many instances these principles are now prepared to our hand in the laboratory, and are supplied in a state sufficiently pure for administration. The properties of our large number are so well known that their genuineness may, with little difficulty, be tested, and fraudulent adulteration detected. These principles we may consider to stand at the present day in the same relative position as regards the practice of medicine as the crude drug occupied in former times—the greater certainty in operation, and potency in effect corresponding with the advance of science in other departments. We have to deal with principles, in fine, instead of the crude material, we reject the inert portion of organic masses; and, casting off superfluities, we advance to the treatment of disease armed with weapons of great power and formidable activity. Another advantage is gained by organic analysis, the detection, namely, of analogous principles in very

many plants, thus showing that numerous individuals of this kingdom are indebted for their place in the *materia medica* to principles identical in composition and similar in effect. Hence we see that, should organic substances be grouped together according to the prevailing or active principle, our memories might be relieved of much unnecessary detail. It will be of comparatively little importance to pay attention to the sources whence they may be derived, such references alone being requisite as will serve to awake attention, rather than confuse the mind. Impressed with these ideas, it appears to me that the *materia medica* may be comprised in a much smaller space than it has hitherto been, and that it might also be arranged in a much more simple and intelligible form. The works upon this subject, which are deservedly in the highest repute, are arranged in one of two forms, either alphabetically or according to the natural-history system.

In either case the natural history of the substance in question forms a large portion of the amount. Such details are essential where the whole subject is to be treated of. The lecturer on *materia medica*, however, at any of our schools, finds himself relieved of the chemical and botanical portion of his labour, and has only to look to that which concerns his special province, the pharmaceutical and medical relations of our drugs. In doing this he has to think always of the active portion or principle, to view it naturally combined with others; to study its character, so as to separate it on the one hand, and recombine it, if desirable, on the other; he has, besides, to trace it in its progress through the system. Now, all these processes and effects are more or less chemical; our pharmaceutical manipulations are purely so; the changes which take place within the body are chemical too, modified undoubtedly by the vital influence. Is the proposed arrangement, then, to be chemical? The *materia medica* ought, I think, to be so arranged, in order to be studied pharmaceutically. It is proposed, then, to place in groups those substances which are distinguished by a certain similarity of composition. But it may justly be asked, is organic chemistry sufficiently advanced to permit us to assume this as the basis of classification? Far, very far, from complete, let it at once be admitted, must be this attempt at arrangement; but, while we allow that we have much to learn before it can be so, no one will deny that much sound and valuable knowledge has been accumulated respecting the composition and properties of the *materia medica*. Should it be granted that such a classification, if practicable, would be the best, we need not, in that case, await the perfection of analysis. When, besides, a chemical arrangement is spoken of, I mean a chemical one so far only as chemistry may give us the broad indications of the properties of the classes which it is proposed to form—properties which it is absolutely essential that the practitioner should be acquainted with, as they regulate all our formulae. In studying the properties and action of drugs, it is not necessary that we should involve ourselves with minute atomic calculations, nor that we should dwell upon the refined distinctions between the different orders of plants and animals. The great and immediate object of this particular department, the *materia medica*, is the investigation of our curative agents, to view them in the simplest manner, and to discard all unimportant considerations. If the fact be admitted that in the cure of disease the result is produced by means of certain organic principles, and we can separate these, then may we discard inert matters, and chiefly direct our attention to the active portion of our medicinal roots, barks, leaves, flowers, fruits, or seeds.

It is proposed subsequently to divide the whole of the *materia medica* into two classes—the organic and the inorganic class. The incontrovertible proofs which we have of the identity of composition of many animal and vegetable substances render the separation of these two kingdoms unnecessary when treating of organic principles. This will be one step towards the simplification

of the subject; and, proceeding from the point to which botany and chemistry conduct us, we may dispense with minute botanical distinctions, however interesting, or classifications of animals, however ingenious. The mind will thus be better disposed to regard the properties of the substance before it, to consider its mode of operating, and the laws which should regulate its administration and use. Let me not be supposed to underrate or decry the utility of studying the laws of vegetable life as illustrated in the formation of those principles upon which eventually animal life depends. In regarding the more simple processes of the germination of plants we discover the reasons of the changes in our own frames, and ascend analogically from the mere combination of elements to the complex metamorphoses of organized principles. Having made these general preliminary remarks, I shall proceed in my next paper to the more practical consideration of my subject.

A COURSE
OR
LECTURES ON SURGERY,
BY
SAMUEL COOPER, Esq., F.R.S.,

Professor of Surgery to University College, London;
Consulting Surgeon to London University Hospital, &c.

LECTURE IX.

The subject of inflammation may be appropriately succeeded by the consideration of abscesses, involving the process of suppuration, often the result of inflammation, though some eminent physiologists, including Andral, are of opinion that it occurs where the latter has not taken place. As it may take place in any of the parts of the body provided with blood-vessels, it occurs in the same localities that are liable to inflammation. It may be connected either with specific injuries or a more generally morbid condition of the system, and leads to the formation of pus. When this purulent matter accumulates in any locality, that accumulation is called an abscess. As suppuration may be a consequence of acute or chronic, common or specific, inflammations, its character is modified accordingly: that suppuration which is brought on by acute inflammation is exemplified in every common abscess following healthy inflammation—in whitlows, milk-abscesses, those following gunshot wounds, and such violent mechanical injuries. Some specific inflammations produce acute suppuration, as seen in the venereal bubo. Others induce chronic suppuration: the lumbar abscess, and most scrofulous abscesses, are chronic, although some may commence with acute inflammation.

Although all parts susceptible of inflammation are liable to suppuration, some are more so than others: the mucous membrane, according to the observation of Professor Thomson, being the texture in which it is most readily produced, as in the lining membrane of excretory ducts, the respiratory or urinary organs. The same causes also which excite cutaneous inflammation and separation of the cuticle may produce suppuration of this texture. It may be induced by various circumstances, some of which are—1. the intensity of inflammation; 2. the nature of inflammation, always leading to the formation of a puriform fluid; 3. by continued exposure of certain internal tissues, as in the case of wounds, the sides of which have not united; 4. as a concomitant or, at all events, a result of ulceration; 5. following slight inflammation in mucous tissues without ulceration or breach of surface; 6. it is possible in parts having a serous membrane, as the disease called empyema, or a collection of purulent matter within the cavity of the pleura, proves: this disease first conducted science to the fact, that suppuration may take place without the destruction of the solids; 7. injury of the texture by violence, attended with contusion, and laceration, as well as the presence of foreign

bodies in the cellular tissue, is a frequent cause of suppuration.

An abscess may be defined to be a tumour containing pus—a collection of purulent matter in the tissue of an organ. Where there is no accumulation, but matter pours out from the surface, there is not an abscess, though suppuration takes place: it is called a discharge. The matter of an abscess is generally deposited in the centre of the inflamed part, and the texture seems to be previously loosened and deprived of its firmness. Its formation is often preceded by a violence and rapidity of inflammation which may often serve to indicate the next stage. The pain and throbbing, the swelling and tightness of the parts, seem to attain their highest state of excitement just at the period preceding suppuration; and, if the inflammation be sufficiently strong to excite fever, it is then that febrile disturbance is greatest. When, however, matter is well formed in the tumour, all these symptoms are reunited, and, instead of an acute throbbing, a dull heavy pain remains. One portion is distinguishable from the rest rising to an eminence, generally in the middle of the tumour, of a whitish or yellowish appearance, permitting by its transparency the subjacent fluid to be discerned. At this part the skin is very thin, and when the pus arrives at the cuticle that texture gives way, and the pus is discharged.

It is a point of the highest importance to a practitioner to have the means of forming a correct judgment on the cases which present themselves under the appearance of abscesses. Nothing certainly marks more distinctively the experienced and observant surgeon than the ability to detect collections of deep-seated matter; and, as ultimately the true character of disorders of this kind is made obvious to all, nothing is more injurious to the reputation of a surgeon than an erroneous estimate of one of these cases. Generally, in an abscess, fluctuation may be discerned before pointing, and where this can be distinctly made out, it is one of the surest signs of the presence of pus, since only under that condition can fluctuation really exist; and it may be sometimes detected, although the matter of the abscess is thickly covered by textures, and lies at a great depth. At other times the thickness of the muscles covering it prevents the practitioner from deriving aid from this symptom. Where an oedematous swelling is observed, which is often the case, it may assist the surgeon in his diagnosis. Sometimes the perception of fluctuation is impeded by the character of the pus itself where it is thick. Many fail in their diagnosis for want of a correct method of conducting the manual examination of suspected abscesses: the fingers are not to be applied successively to the two sides of the tumour; but while two or three fingers are placed on one side, the opposite side is to be tapped with those of the other hand: in this way, where fluctuation exists, it will be rendered more or less susceptible, according to the circumstances which have been enumerated.

But the mere manual examination of a tumour, however useful and, indeed, indispensable, should not be altogether relied on; the history of the case may be always made to contribute to the formation of a correct opinion upon the case; every symptom must also be compared with similar appearances, and their differences discriminated; and these, joined to the information derived from the manual examination, will generally conduct a man of observation and reflection to a correct result.

Besides these local symptoms, there will be, in many cases, frequent shiverings or rigors, following symptomatic fever. These rigors, however, seldom occur, unless the collection of matter is considerable or in some of the internal organs. The constitutional disturbance is afterwards lessened, and, instead of acute pain, numbness is felt. If, in addition to this, the patient have nocturnal exacerbation, sweatings, and a small quick pulse and hectic symptoms, for which no other cause can be assigned, they are

additional grounds for suspecting the existence of an abscess. The rigors, it has been observed, seldom occur very distinctly, except where the collection of matter is considerable, or where some of the viscera are the seat of suppuration. Hunter remarked that they are more common at the commencement of spontaneous inflammation than in that which arises from outward injuries.

When the patient is of acrofulous constitution, a very slight increase in the action of the vessels will be followed by the formation of matter; indeed the first intimation of such increased action may be given by the appearance of such an abscess, as it may take place without much disturbance in the part; and in this respect they differ very much from those formations which follow acute inflammation, in which all the symptoms are aggravated just before matter is deposited, but which subside on the establishment of suppuration. Up to that time the arteries become dilated, causing the sensation called throbbing, and marking the transition from adhesive to suppurative inflammation: the colour of the part also becomes heightened, and is of pale scarlet hue; the swelling and tension increase through the dilatation of the vessels and the effusion of coagulating lymph.

The pointing of an abscess, which arises from the approach of matter to the surface, occurs earlier or later, according as the inflammation is more or less acute, and must be preceded by a gradual absorption of the parts lying between the collection of matter and the skin. After having made its way through the cutis, its passage may be delayed for a time by the thickness of the cuticle, which by the intervention of the pus is divided from the cutis; but it ultimately bursts, and the matter escapes; the tightness is thus relieved, and the feeling of weight is gone. The discharge may continue for some time, and the size of the opening increase, but under favourable circumstances the cavity diminishes, the acche-nous inflammation and granulating process ensue, and the opening heals up.

There may, however, be causes in operation to prevent the healing of the opening: thus, the presence of a foreign body, diseased or dead bone, retained pus, or the nature of the disease, may take away the disposition of the opening to close. The passage by which the abscess communicates with the surface is called a *fistula*.

It is desirable that you should be put in possession of the opinions on the theory of suppuration of those who have devoted and applied considerable time and talent to the subject, and more so, as the most discordant opinions have been held by pathologists respecting it. It was for a long time thought that pus could dissolve and hold in solution the living solids of an animal body; but, were that true, no sore discharging matter would be exempted from continual dissolution, and an abscess must continue to increase either opening as fast as before. It was upon this principle of the dissolution of solids into fluids that the practice of bringing indurated parts to suppuration, rather than making an early opening was founded. The experiments which men of more recent times have made for the purpose of building up a gratuitous theory, instead of proceeding boldly in investigating Nature, have made their conduct still more ridiculous: those who put dead animal matter into abscesses, and, finding a part dissolved, imagined they had arrived at a confirmation of their theory, because they had proved the power of living matter over dead, must also have known that even extraneous animal matter will lie in an abscess for a long time without dissolution taking place, and that in some kinds of abscesses sloughs of the cellular membrane come away like wet tow, and, therefore, did not form pus. So the formation of pus has been ascribed to a fermentation of both solids and fluids. If so, how can what happens in internal canals be accounted for, where pus is formed without loss of substance or previous fermentation? Whence, also, could the solids come which enter into the composition of urethral discharges in gonorrhoea, since the whole

substance of the veins could not afford matter enough for the pus of one gonorrhoeal discharge? How could such a process ever stop? And, yet more, how was the first particle formed?

Nor is that theory which accounts for the formation of purulent matter by the conversion of extravasated blood more tenable, since blood has never been known, when extravasated by violence or rupture of a vessel, of itself to become pus; nor is it known that pus, in these cases, was ever found without previous inflammation.

That particular doctrine of the process of suppuration which has found most favour in the present day ascribes it to an action of the vessels analogous to secretion, and the arguments by which it is supported, I think, are well worthy your attention. It is known that suppuration is influenced by many circumstances affecting secretions in general. For instance, an ulcer, while pouring out a white, thick, healthy matter, becomes suddenly inflamed, the discharge diminishes, and becomes thin and reddish—a fact which agrees with the effect of inflammation in modifying the natural secretions in the organs which are the seat of it. So, also, the quantity and quality of the discharge from an abscess are often changed by violent emotions—sudden fever, the state of the digestive functions, and the diminution and decrease of the secretions by the influence of the nervous action in the system; and by functional or organic disorder in a part of the system unconnected with the seat of suppuration; and when it is considered that the kind of pus secreted varies with the peculiarities of the organization of individuals, the analogy is still more obvious. Those who hastily reject these views because no pus is found mixed with the blood in the system, following the same argument, might deny that the bile is a secretion, since it can, under no circumstances, be found in the blood. Neither pus nor bile is in the circulation, but the matters which, by the action of the secreting vessels, are converted into one or the other of those fluids.

From the fact that pus forms from the surface of the cutis, or a mucous membrane, without ulceration, it might be inferred that a dissolution of solids is not essential; but, although not necessary, it may accompany suppuration. Perhaps a portion of that substance which we find loosened in abscesses may occasionally be blended with the matter. There was several years ago a girl in Bartholomew's Hospital who had an abscess in her hip. When this was opened, with the pus a considerable lump of adipose matter came away. No doubt it was merely an accidental addition, and not an essential part of the purulent matter. When we examine the interior of an abscess, the cavity is found to be lined with a smooth membranous substance, of whitish ash colour: it is called the cyst or sac of the abscess. The cellular membrane surrounding it is denser and more vascular than in its natural state; its cells are closed by coagulating lymph. By these two conditions, one of the sac and the other of the surrounding cellular substance, the matter of the tumour is bounded and prevented from becoming diffused. Abscesses have a tendency to make their way to the surface, and discharge there, by which tendency they will frequently make their way through a considerable thickness of parts lying between them and the skin, although merely a delicate serous membrane divides them from the cavity of the belly; they will, however, sometimes burst into a neighbouring duct, lined by a mucous membrane; and in this way those which form near the urethra or rectum take one of those outlets, as being the most direct course to obtain an outlet from the system. Where dense fascia exist between the abscess and the surface, great mischief will often ensue: unless precaution be taken, the purulent matter spreads between the muscles and under the fascia, forming formidable sinuses, greatly impeding a speedy cure.

Dr. Raymond, medical professor to the medical faculty of Madrid, died recently very suddenly.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILLSHIRE, M.D. (Edin.), M.B.S., Physician to the Royal Infirmary for Children, &c., &c.

(Continued from p. 270.)

GENTLEMEN.—In my lecture to-day I shall continue the consideration of the general internal or constitutional treatment of scrofula, afterwards alluding to that especially adapted to the more important groups of its external manifestations. When I last addressed you I referred to the general characters of those remedial agents which were found to be the most serviceable, and I remarked that they were such as are indicated by the terms of *tonics*, *alteratives*, *liquefacients*, and *deobstruents*. Passing over *iodine* and a few other agents, supposed by some to exert almost a specific power over scrofula, I may say that the tone-giving agents you will find most serviceable in treating the malady are *iron* and *quinine*, and these may be given in various forms and modifications. You might expect, perhaps, that, from the known action of iron upon the blood, this metal would be of great service in correcting the thin serous fluid wanting in proper plastic material met with in this disorder: and it is the case that under its use the circulating fluid becomes richer, thicker, and richer in colour and fibrinous material. This improved state of the blood naturally reacts upon all the organs and textures of the body through which it circulates: it affords them new and better material to repair their wear and tear, and to increase their size, at the same time that it is wanting in that from which morbid deposit would certainly take place, did it exist. You will find, I am sure, from experience, that the preparations of iron are amongst the best agents you can have recourse to in this disease. The results of clinical experience also receive great support from physiological experiments. You will remember, perhaps, that I told you M. Coster placed a number of dogs, rabbits, &c., under the circumstances most favourable for the development of scrofula. Many of these unfortunate animals were shut up in dungeons without light, or space, or motion, and exposed to a cold, moist atmosphere, by means of wet sponges hung up in the cages. Some of the animals were fed on their ordinary diet, others were fed with food containing iron in the proportion of half an ounce of the sesquioxide to the pound. All the former became ill—the greater part were tuberculous; but not one of the latter afforded a trace of tubercle. I am the more particular in impressing upon you my belief of the value of iron, because it has lately been promulgated by a very great authority on the diseases of children, in France—M. Trousseau—that this agent is one of the worst you can administer to a chlorotic girl, in whom there exists disposition to tuberculous deposit; and in fact, from what I can glean from his paper, he regards it as to be entirely set aside in the treatment of incipient tuberculosis. M. Trousseau also affirms that there is a species of antagonism between chlorosis and tuberculosis—a repugnance between these two affections to exist together. If you give iron, he says, in such a case, it restores to the blood its exciting qualities, provokes febrile action, and hastens the end of those destined to die of phthisis. Now, I can neither believe in such antagonism, nor in the view here held of the effects of iron. Every one will admit that the indiscriminate employment of iron in certain cases, although it may give support for a time to the general vital energies of the body, may yet tend to increase the local derangement; but that in a pale chlorotic girl, of flabby muscle, with a loud *bruit de soufflet*, iron is at once to be abrogated—is the very opposite of a doctrine I should wish to inculcate.

Iron may be given at all ages, but certain forms are more fit for one age than another. When the child is old enough there is no form better than the sesquioxide; I prefer this form to all others; you can give it in treacle, in doses varying from a teaspoonful to three teaspoonfuls

in the day. For very young children I prefer the *vinum ferri*, and this you may give to children at the breast. I am aware that this preparation is ridiculed by some, who regard it as of little use, and think it properly discarded from the Pharmacopœia. They say, that if it does any good it must be from the *vinum*, since it contains only a very little tartrate of the sesquioxide. Be this as it may, whatever it contains I know that it contains enough iron to change the colour of the dejections, and also sufficient to do a great deal of good in a child of scrofulous constitution.

Some practitioners are fond of the *tartrate*, and others give the *tincture of the sesqui chloride*. The *tartrate* is a good form. The *tartrate* and the *citrate* may be given to very young children, and are useful too on account of their bitter flavour. I shall speak of some other forms presently.

Quinine, I remarked, was a very able weapon in strengthening the scrofulous patient. I prefer it generally to the *bark*. In some cases it seems to do more good than anything else, especially in those where there is great loss of appetite, but not evident fever. Care must be taken that too much acid is not used in dissolving it when the intestinal lining, membrane is irritable. You will find the addition of the tincture of hyoscyamus or of haddock very often advisable. I think that this agent in combination with the *sodide of potash*, is the grand remedy for scrofula. I shall allude to it more fully presently, but I may tell you I have more faith in this combination than in anything else. Maunsell and Evenson state that a combination of cinchona and iron is often more serviceable than where either is given singly. It was first proposed, I think, by Dr Cheyne. I have given quinine with the sulphate of iron, adding a little sulphuric acid to the mixture, with great benefit in some cases. For children of the better classes of society you will find the *syrup citrate of quinine and iron*, manufactured by Mr Bullock, an admirable preparation. You must not think, however, that it is so very nice, as its name of syrup citrate seems to indicate, for, when mixed with water, the more powerful flavours predominate. Still, for those who can afford to pay a little more, I strongly recommend it. As a general rule, you know, for young children, medicine should be made as nice as possible, but the metals and quinine are no very easy to deal with in this respect.

Although you will find *iron* and *quinine*, with their combinations, so useful in scrofula, you would be wanting in a still more efficient weapon if you had not *iodine*. This, gentlemen, is the grand remedy in struma. I need not detain you with any descriptions of it—chemical or pharmaceutical—you will find such subjects amply spoken of in the various modern works on *medicines*.

We have now had a little more than a quarter of a century's experience with this agent, and I think that such experience warrants us in believing that the scrofulous disposition or disease meets with an antidote in iodine. By the latter, not only the present malady is cured, but future ones are avoided. In using iodine, you of course are not to expect to always overcome everything before you, but you will overcome much that you could not with its most important aid. My experience in its use is great, my belief in its virtues is so also. I have had plenty of children brought to me with bad scrofulous ulceration, which was in various stages of the various modes of treatment they had been subjected to, when I gave iodine the sores healed. I have had enlarged cervical glands to treat over and over again, in which cases no iodine had been used and they remained, in spite of every other thing, as hard and as large as ever. When I gave iodine they got well. I have seen chronic skin disease in scrofulous children resist treatment, I have administered iodine, and the skin became clear. I have had children with struma in the parotid glands, of the mammary glands, successfully treated by it, and chronic hydrocephalus has yielded to its

power. Now, I will go further than this, and say that how vast a world far between they have been, I have had recoveries for a time from infantile phthisis, and have ward off the more severe symptoms of that lethal disorder, tuberculous meningitis by the use of this most valuable drug. I have painted the surface of sores with its alcohol solution, have rubbed it over joints, oozed it over tonsils, have had many young children shaved, and then rubbed with its ointment at night and morning for months together, in fine, from what I have seen of its power, I regard it as one of the grandest agents of the Pharmacopœia. In this opinion I do not stand alone, many others are as deeply impressed with its power as I am, and no one more so than M. Lugol, who ascribes iodine to be possessed of powers as strongly opposed to scrofula as mercury to syphilis. But there are others who regard it with a far more doubtful eye. They see nothing very peculiar in it, believe in no antagonistic or specific virtue of it and hold other remedies to be quite as effectual. It may be all very true that Myogenic took a quantity of the tincture, containing nearly a scruple of iodine, without its producing any effect. But Dr. Kenney has administered it in a case in which we thought given doses daily, giving in the whole 900 grains, without any benefit, or that, on the other hand, a patient has been a miserable sufferer from the effect of iodine, that in other cases they have got worse under its use. That is uncertain both from its own peculiar variability of power and its commercial adulterations, and that, more than all, its virtues cannot be depended upon, since by its mixture, with bread, potatoes, sugar, arrowroot, tincture or other like matters in the stomach, these virtues will be modified and diminished by the formation of an iodide of starch. I say admitting all these and other theoretical and practical objections which exist, yet in spite of them there is nothing equal to iodine in the more therapeutic treatment of scrofula. According to Condet, it is most useful in the torpid, in irritable, and chronic form of the disorder, or what the Germans call *calde scrofula*, Wutzer is of the same opinion and these writers along with Solbergheim, rather depreciate its employment in what they call scrofula with exanthem or inflammation of struma. Hufeland and Gracile value it chiefly in the pusillous lymphatic variety, and believe it to be detrimental when there is much pain, increase of temperature, great redness, tension and hardness of the diseased part.

If in my own experience I should say, that unless the inflammatory action going on is very intense and much febrile exanthem present, there is no reason why iodine should not be given and it is just as useful as when the diseased part is devoid of all redness or discoloration. Bearing in mind that in the former case we have a more advanced form of the disease to deal with. In cases where the attendant hectic runs high iodine is certainly contraindicated, except in very small doses, and in particular combinations. But as regards the local forms, such as swollen cervical glands &c., with discoloration, heat of skin, or even suppuration with active local symptoms, there is no reason that iodine should not be given internally as well as when those symptoms are wanting, though, of course, its topical application is sometimes impossible. I have seen scrofulous ulceration, attended with great local irritation, heal most rapidly under the use of this drug, whilst under other agents it was increasing. But this is a grand point for you to recollect, that in scrofulous patients affected with an active form of disease, the attendant inflammation was of the common or sthenic type, then the iodine might be contraindicated, but this you know is not the case. The inflammatory action is of a peculiar, a specific form, and only occurring in a particular constitution, and against the tendency of such a constitution iodine wages war. The inflammation being a local manifestation of a general diathesis, iodine is to be employed in curing it. As to the question whether iodine does not exert more power in those cases where

the action is more chronic, less active in its character, is another thing altogether—generally I think it does, but this is not a reason why it is contraindicated in the opposite varieties.

Some persons have endeavoured to deprive iodine of its reputation, because, in the practice of those who have gained so much good from it, great attention was paid to general hygienic treatment, and to the latter alone would they award the praise. But I think it might be asked. Will iodine, in cases almost totally deprived during treatment of proper hygienic care—as in the poor patients of dispensaries, &c.—do more good in the greater number of them than anything else? To this the answer must be in the affirmative. Of course, if much good be seen to accrue from it under such circumstances, still more will be experienced when it is combined with the hygienic treatment I have already recommended, and which has been so successfully put in practice by M. Lugol. But so will more good be found to arise from the use of colchicum in gout if the patient will drink talc instead of Madeira, more benefit from tapping in pneumonia, if combined with antimony, calomel, and opium. In fact, the same rule may be applied to every drug, in complicated instances requiring treatment.

Although I would impress upon you a very high opinion of the powers of iodine, at the same time you must remember that there exists no universal remedy which can answer all the indications met with in the numerous phases of this disease, but that dietetic and hygienic regimen the improvement and alteration of the digestive functions by bitters, aromatics, and neutral salts, and modifying the crasis, &c. of the blood by preparations of iron, are to be had recourse to, along with iodine itself. I pay due attention to these principles much of the value obtained from this agent will depend, and in many instances you will find that, unless it be combined with quinine, or an alkali, your progress will be slow, but, on these being added, improvement of the patient becomes sure. But still you may often give alkalis from quinine, &c. and for a long period and until iodine is resorted to, amelioration is slow in the extreme, if at all. This proves in my opinion, the fact that this drug has more power over the constitutional tendencies than any other, it somehow combats more ably the abnormal states I have told you about, than does anything else. But, inasmuch as numerous steps and stages of diseased action and local changes are involved in all cases where we have open and tangible forms of scrofulous disorder, so do we have many indications and one remedy, even though it be scarce, may not be equal to all, and therefore do we see reason to combine its administration with that of something else.

Iodine may be given at any period of life, it does not matter whether the patient be a month or fifty years old, and it may be used internally or externally. A very great difference of opinion exists as to its proper doses and the relative value of the combinations, some give it in large doses, others in very small. Although I am not so frightened of large doses as some persons are, I prefer greatly, small ones, not that I dread much the production of "iodism," or "iodinous erythema," but chiefly gastro-enteric irritation, from which the patient will be forced to suspend, or entirely give up, a most useful agent, before it has had time to affect the constitution. In those large doses, recommended by some, it has such a tendency to pass off by the kidneys, and sometimes by the bowels, that very little of the drug gets into the system so is passed into intimate combination with the tissues of the body.

I generally prefer giving the *sodide of potassium* to any other form, sometimes I add the iodine itself to the solution. But I find that in children I can continue the former by itself much longer than I can any other state of this drug. You will find that to the youngest children one grain of the *sodide* in distilled water, sweetened at the time of administration, may be given three times a day with safety and advantage. If

the child be a year old you may add from 1-10th to 1 8th of a grain of iodine to the solution, if deemed requisite. Your doses will go on increasing up to three grains of the iodide of potassium with 1-3rd of iodine, according to age and other circumstances. The vehicle I recommend you is distilled water, and the mixture may be sweetened when it is given, not before, for decomposition will ensue in a short time. According to some, the iodine and iodide of potassium ought to be given in large quantities of liquid, or else, in all probability, a precipitation of the pure iodine will take place when it comes into contact with the gastric secretions. From small quantities of *vehiculum* I have found no inconvenience result, and a small amount for children is a great thing, you know.

I have alluded before to a combination of *guaiacum* with the iodide of potassium, and thus I recommend you, with the strongest assurances of its value. It is a combination which I can safely say I have seen do wonders in the more chronic cases attended with much debility—I know of nothing like it. The mixture is certainly not chemically proper, some iodine is set free especially if there is much excess of sulphuric acid in the solution. But this does not hinder me from using it, as I know it is a double therapeutically considered, in fact, many of the combinations and forms in which iodine is given are not right, chemically viewed, but I think in practice they are highly valuable, *water* for instance, only dissolves 1-7000th of its weight yet you may give it in this vehicle sweetened with syrup at the time of administration.

For external use I generally employ the compound ointment of the London College rubbing it over glands, the scalp, &c., undiluted, in the young child needing it. Very rarely, and, indeed, have I found it too strong. When a solution is wanted I employ the compound tincture and generally undiluted. I have now and then used a lotion of the iodide of potassium in distilled water, varying from 5 gr to 3j to the 3j of water. In particular cases, when you wish to produce much counter irritation, I recommend you the following:—

Dissolve 3j of iodine and 3jss of the iodide of potassium in 3ss of alcohol. This may be painted near the affected part, and vesication will ensue.

With iodine and the ioduretted iodide of potassium, I always find I can answer most indications, and when *guaiacum* is added to the iodide, I want no other form of the iodine combinations. But other persons, you know, often use the iodide of *iron*, the *proto iodide* and *bio iodide of mercury*, the iodide of lead externally, and various other forms. For information upon these agents I must refer you to *Parry* and others.

Some have great faith in the *chlorides of barium* and of *calcium*, as also of *salutary* and others in *arsenic*, *silver*, and *gold*. I never employ any of these except here and there *arsenic* in certain cases of chronic skin diseases in the scrofulous child. I do not doubt but what the others may do good, but I am so contented with *iodine* that I prefer adhering to its use alone.

Of the *alkalis* and *mineral acids*, and of *hemlock* and other narcotics, all of which have at times been vaunted to the skies, I have nothing particular to say. There of course exists plenty of indications for their special employment, under different circumstances, but they have no special relations to *scrofula*, that I am aware of.

There is one agent I must not forget to speak of, viz. *cod-liver oil*. This has lately been much praised. I have administered it in about twenty cases, not more, and certainly found benefit from its use. Many persons speak very highly of it indeed, but, after all, I think its reputation will greatly subside. You may begin with a teaspoonful of it three times a day to young children, gradually increasing it. You may use it *undermedically* also.

Bromine is rising in reputation. *Pepsin* was once used. The *extract of walnut-leaves* is a

powerful weapon in the hands of some practitioners, more particularly abroad.

Now, gentlemen, in the above agents you will find many besides *iodine*, *iron*, and *guaiacum*, that I have no doubt you may use with great advantage. Whilst you are doing so, of course you will have to attend to the state of the bowels, &c., but in no form of *scrofula* do you want active purgation but in one—viz., in *tuberculous meningitis*—here there is often obstinate constipation, which you have to overcome, and also to keep up continued peristaltic movement. For this purpose I think you will find that at first aloes, with the sulphate of potassium, will be the best combination you can give, afterwards, the barba with jalap. In other cases *rhubarb*, with the sulphate of potassium with *soda*, and often combined with the *julep of columba*, will be found very serviceable. In many nothing is better than, simply, *castor oil*.

I must now caution you against what you are not to do. This is not to give *mercury* in *scrofula*. I state the *general rule*, mind! I do not mean to affirm that a grain or two of *hydrargyrum*, with a little *rhubarb*, *soda*, or *columba* given at bed time, for a few nights, is always bad practice, on the contrary, I think it is often very good. Oh, again, that small doses of the *iodide* in the compound tincture of *cinchona* is not often serviceable—far from it, what I would imply is, that in children *hydrargyrum* continued day after day, or week after or the putting of the child under a *course* of *mercury*, is not only useless, but highly detrimental, that *hydrargyrum* not only endavouring to affect the system by it, it possible in *scrofula* is in 99 cases out of 100, bad practice indeed. If it be true, and I believe it is, that after the absorption of *mercury* important changes are effected by it in the qualities of the blood and in the action of all organs, more especially those of organic life and that these changes are of such a nature as to do anything but effect what is so desirable in 99 cases out of 100 of *scrofula* its use will receive no support from reasoning *a priori*. If it be true that under the use of *mercury* the coagulability of the blood be diminished the proportion of clot, and therefore of fibrine and serum, becoming smaller, if the formation of albumen and mucus sink to that of serum, and the whole organic functions of the patient become less consistent, less cohesive (*Dietrich*) if *mercury* diminishes the number of the red globules of the blood (*Hart*), if it changes the negative, healthy, electrical condition of this fluid to a positive one (*Dietrich*), if it be a weakening agent as *Leitch* (*Smith, Hertlo*), if *mercury* be, or be all this, why is it useful in *scrofula*? "A full, phlegmatic woman, of a purple red complexion, consulted me for hemorrhage from the stomach, depending on engorgement without organic disease. I gave her *mercury*, and in six weeks blanching her as white as a lily."—(*Lancet* 1st series in the Diseases of Women.)

I should be, however, one of the last to ask for a *priori* or theoretical reasons why a special drug should be given in any disease so long as *experience* told us it really was useful, and therefore, though *mercury* did to all these and many things more, and yet cured *scrofula* I would use it, but does it? What form of *scrofula* does it cure? Does it cure tuberculous phthisis, meningitis, peritonitis, or disease of the uncalcified tissue of the bones? Does it heal up scrofulous ulcerations, or diminish enlarged cervical glands? Does it improve in general appearance the poor little meagrely diseased remains of an offspring of the miserably poor tea-drinking, meat-wanting washerwoman? Does its face become clearer in its complexion? Do the legs become firmer, and their flabby hanging folds of turgid filled up and tense? Or does not *mercury* still further debilitate its system and give rise to fresh outbreaks of scrofulous disease? I believe it does. I should tell you that, in the Dublin School, there has arisen a class who, in certain cases of tubercularization, advise a "rapid mercurialization" to be had recourse to, chiefly,

I believe, in certain cases of pulmonary tubercularization and of a tofulous inflammation of the hip and knee joint. There is not a better practical school in the world than the Dublin, but in this I should decline following it.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF MEDICINE.

Meeting of June 1, M. BOULIARD in the Chair.

GOVERNOR.

A report was read by M. Gibert on a paper by M. Worbe, a military surgeon. The object of the communication was to propose a method calculated to prevent the contagion of venereal diseases, and to arrest them at their outset. The plan recommended by Dr. Worbe consisted in treating with a weak solution of corrosive sublimate, a fluid which he also considered as the best injection which could be used for the early removal of gonorrhoeal discharges. Dr. Worbe had not founded his opinion upon any experiments, but merely upon induction. It did not rest upon any other proofs than those which the author derived from a chain of reasoning, plausible, it is true, but insufficient to demonstrate its accuracy in the absence of facts. The reporter, therefore, merely proposed the thanks of the Academy to the essayist, and that his paper be deposited in the archives of the society.

M. Velpeu examined successively three questions connected with the subject. Could chancre be arrested in their incipient state, such a way as to render general treatment by mercury unnecessary. The reporter seemed to think so. M. Velpeu himself believed it was possible, but that it was extremely rare. If chancre was a purely local disorder it certainly might be destroyed with safety, but how long did it remain local, what was the length of time during which cankerization might still prevent the penetration of the syphilitic poison into the system? These were points which were unsettled. The second question towards which M. Velpeu would direct the attention of the Academy was that of chancre in the urethra. M. Velpeu had seen many persons with secondary and tertiary syphilis twenty or twenty-five years after simple gonorrhoea; their numbers were too great to permit of them all having had urethral chancre. M. Velpeu therefore was disposed to believe that gonorrhoea might be syphilitic without chancreous ulceration of the urinary duct. With regard to the native treatment of gonorrhoea, M. Velpeu would say that the solution of nitrate of silver of an arrested blennorrhagic discharges in a few days.

After some remarks by M. Adelon and M. Richoux, M. Coquet stated that he had for many years abandoned the method of cankerization of chancres at an early period of their existence, because he had in several instances found that it had led to the formation of bubo. M. Coquet was of opinion that one-third of urethral discharges was syphilitic, another third herpetic (*dartreux*), and the remainder of a simple inflammatory nature. The great difficulty was to distinguish these varieties from each other.

M. Roux felt the most profound conviction that in syphilitic gonorrhoea the urethra was not ulcerated. As to the sudden suppression of urethral discharges, he was of opinion that gonorrhoea should in a great measure be abandoned to its nature, and that the methods employed for its rapid termination materially increased its dangers.

M. Gimelle stated that in the course of six years he had the good fortune of curing four patients affected with gonorrhoea, in none did he find any ulceration of the urethra.

M. Renaud said that he had been a long time engaged in researches for the purpose of ascertaining the precise period of general infection in cases of farcy in horses, and what was the effect of cauterization of the primary sores on the intoxication of the system. The analogies between farcy and syphilis were numerous, and

gave some value to his experiments. Cauterization of the primary sores, twelve hours after their first appearance, was insufficient to prevent the passage of the morbid poison into the blood.

M. Lagneau did not believe that cauterization of the primary sores in syphilis could destroy their specific nature. Out of ten thousand cases of gonorrhoea, M. Lagneau did not think that more than one could be found of urethral chancre.

M. Rochoux agreed with the preceding orators; out of a thousand cases of gonorrhoea not more than one perhaps presented chancre in the urethra.

The conclusions of the report were then adopted.

MUSCULAR CONTRACTION.—WRY NECK.—M. Bouvier communicated a case of ancient muscular contraction, with the *post-mortem* examination. A man, aged eighteen, received, at the battle of Trafalgar, a blow on the neck from the fall of the yard of a ship. The injury was followed by stiffness of the neck, which was drawn towards the left side. The contraction lasted forty-two years. On dissection, the sterno-cleido-mastoideus muscle was found to have lost nearly one half of its length, and to be considerably modified in its texture; the arteries and veins were altered in their shape and in their course, and the vertebrae were also much changed in their form.—Meeting adjourned at five P.M.

ACADEMY OF SCIENCES.

Meeting of May 31; M. BROGNIART in the Chair. **EFFECTS OF THE INJECTION OF VARIOUS SUBSTANCES INTO THE ARTERIES.** BY M. FLOURENS.

In a former communication we stated that, having injected ether into the arteries, M. Flourens found that its effects on sensibility and motility occurred in inverse order to those resulting from inhalation. Inhaled ether destroys sensation before motion; the contrary is the result of the injection of that substance into the vascular system. In his present paper M. Flourens stated that, having repeated the same experiments with acetic and oxalic ether, with alcohol, sulphuric acid, and ammonia, severally, the same facts were observed as after the injection of sulphuric ether: for instance, six grains of ammonia diluted in 5j. of water were injected into the left femoral artery of a dog, in the direction of the heart. Instantaneously the posterior extremities were paralyzed. The sciatic nerve was then exposed; when it was pinched, the animal uttered violent screams, but no movement whatever was noticed, excepting some extremely weak fibrillary contractions. Oxalic and acetic ether, alcohol, and sulphuric acid, yielded precisely similar results. The injection of 5ss. of essence of turpentine in the right femoral artery of a dog produced effects slightly different from those above described. Loss of motion was accompanied by a state of violent tetanic contraction of the muscles. The injection of 20grs. of nitric ether caused immediate death.

Having thus discovered substances which paralyzed motion without impairing sensation, M. Flourens had not desisted of finding others endowed with contrary powers, viz., capable of destroying sensation without affecting motility. With this view, he tried the effects of an aqueous solution of the extract of belladonna: its results were negative. But it was not a little remarkable that, after this failure, the powder of this root of belladonna yielded the effects sought for, and in the highest degree: six grains of this powder suspended in 3ss. of water were injected into the right femoral artery of a dog, and immediately motion was lost in the posterior extremities, but the sciatic nerve having been exposed and irritated, the animal betrayed no pain whatever, although fibrillary contractions were present in a most evident manner. Powdered hemlock, four grains; valerian, four grains; pepper, two grains; Spanish snuff, two grains, produced exactly the same effects. The essayist was led by these experiments gradually to try the most inert and inoffensive powders, such as oak-bark, lycopodium, and liquorice root. Thus,

four grains of the latter, suspended in 3ss. of water were thrown up into the crural artery of a dog; the sciatic nerve was pinched, torn, lacerated, the animal giving no sign whatever of pain; but fibrillary contraction persisted throughout. These experiments, added M. Flourens, were all repeated frequently with unvarying results. In a physiological point of view, none were more surprising, and none, perhaps, were more certain.—Meeting adjourned at five.

HOPITAL DU MIDI.

CLINICAL LECTURE. BY M. RICORD.

The singular remarks made at the Academy of Medicine, June 1, on the subject of syphilis, warrant us in reproducing the following lecture, delivered by M. Ricord on June 6, in answer to the various allegations made against his doctrines.

At a recent meeting of the Academy of Medicine various questions connected with syphilis were brought before that illustrious society, and opinions which we cannot possibly coincide in having been expressed by men whose views are in general entitled to a high degree of consideration, it becomes our duty to show you the fallacy of its air of reasoning which led to erroneous conclusions. One of the points upon which all seemed to agree was the identity of nature between gonorrhoea and primary syphilis. M. Velpeau, for instance, stated positively, that urethral discharges might be productive, like chancre, of secondary symptoms: no ulcerations existing in the urethra. In support of this assertion, the learned professor added that he had seen many persons labouring under secondary and tertiary syphilis twenty and twenty-five years after a simple gonorrhoea. Now, we would ask, did Professor Velpeau positively ascertain that the patients had never been affected with any other symptoms but a simple urethritis? Is it not by the assertion of the patients themselves and is that assertion sufficient to establish the fact that simple gonorrhoea alone was present? Considering the difficulties which are occasionally met with, even by the most experienced and able practitioners, in the diagnosis between simple and chancreous gonorrhoea, we should say the unsupported assertion of the patient was decidedly insufficient, and must go for nothing. What! a stonemason is affected with orchitis, and, when interrogated on the fact, says that twenty-five years previously he had gonorrhoea; and further attests that it was a simple inflammation—a word of which he is incapable of understanding the value—and his assertion is to be blindly credited! The supposition is too absurd to require further notice.

M. Cloquet goes more roundly to work. He has never met with urethral chancre; we are sorry for it, but not for his sake, as he seems to be quite easy in his mind as to the nature of urethral discharges: one third is simple, another third is syphilitic, and a last division is herpetic. This science is established; we have nothing more to do than to burn our books—a perusal of which we would, however, previously recommend to M. Cloquet, and to treat in an arbitrary manner every three cases, according to this elementary, we may add simple, division. It would not, in our opinion, lose any part of its value, if the learned surgeon would also furnish us with the means of distinguishing from each other these herpetic, syphilitic, or simple gonorrhoeas.

What shall we say to our master, Professor Roux? He places his hand upon his heart, and declares he feels the most profound conviction that in syphilitic gonorrhoea the urethra is not ulcerated. For convictions we entertain the greatest regard, especially in surgery; points of faith are not to be discussed, and against implicit belief we can find no argument. M. Gimelle in six years has had the good fortune—(6 Moliere, greatest of comic writers!)—the good fortune of losing four patients affected with urethritis, and in none did he find chancre. M. Rochoux adds, that not one case in a thousand presents urethral chancre. Whilst M. Lagneau,

enlarging with his subject, cannot believe that one ulcer will be found in ten thousand! We must acknowledge that we should vastly like to see the statistics on which these assertions are based; but, as we do not think they have been ever brought to light, we must consider them as having been strictly confidential, and closely concealed in the capacious intellects of the two learned orators, and given to the world only in an unguarded fit of enthusiasm.

Such are, gentlemen, the various arguments which were brought forward in order to prove the identity of gonorrhoea and chancre: can we call them arguments? We leave them to your appreciation. Let us now lay before you the reasons which induce us to form in this question an opinion altogether dissimilar from that adopted by the academicians we have quoted. In the first place, simple induction: the mucous membrane of the urethra enjoys no immunity from inoculation of chancre: if chancreous pus finds its way into the urethra, and comes into contact with the slightest erosion or laceration, there is every reason for supposing that here, as elsewhere, a chancre will be the consequence; doubtless, this should be much less frequent than simple inflammation; and we may also notice that the cases of secondary syphilis in which the chancreous origin of the disease is not detected are comparatively rare; but it is not reasoning alone which shows the possibility of the existence of chancre in the urethra: ocular demonstration is sometimes obtained. Gonorrhoea is not, thank Heaven, usually a fatal disease: still, we have had what we cannot call the good fortune of losing two cases of gonorrhoea since the last fifteen years, and in those two cases we pointed out the presence of chancres, numerous and characteristic: they were presented to the academy by ourselves, and their existence officially admitted by the reporter of the commission named to investigate the matter (the same M. Lagneau, whose memory seems to have failed him on this occasion.) Besides, it is not necessary that the surgeon should have the good fortune of losing his patients for the purpose of convincing himself of the existence of urethral chancre in cases of syphilitic gonorrhoea. The signs of this affection, which we will in a few moments recall to your memory, are sufficiently well marked to leave no doubt on the mind; inoculation can assist in giving further proof, and often the chancre, at first concealed in the canal, extends towards the meatus, and, appearing at the orifice of the duct, completes the demonstration. We are not, therefore, like M. Cloquet, satisfied with merely dividing gonorrhoea into classes; we also add the signs by which they are to be distinguished. In gonorrhoea virulenta (always the result of chancre in the urethra), what is called the period of incubation is longer than in simple urethritis: that is to say, that the discharge from a chancre is during the first days of its existence so trifling as not to be noticed. The secretion is of a smoky rusty hue, and of a thin watery consistency. One lip of the meatus is usually puffed, and on pressure of the glans penis between the finger the seat of the chancre is readily ascertained by its distinct and circumscribed hardness. When the sore is not far removed from the orifice, it may also sometimes be seen by separating the lips of the meatus, or by the use of the speculum urethrae of Sigalas. All these signs give a well founded probability of the existence of chancre, but an absolute certainty can be obtained only by having recourse to inoculation.

Such are the motives which lead us to differ *toto caelo* from the opinions so unhesitatingly laid before the academy: in that illustrious body, to which we have not the honour of belonging, we have no opportunity of explaining our views; and we could not permit you to be misled by what we consider to be fallacies, particularly when they are placed under the patronage of names which we are taught justly to respect.

TREATMENT OF TENIA.

A woman, aged thirty-three, was admitted into La Charité on the 4th of April, in the wards of M. Rayer; she had been since fifteen years of

age suffering from the presence of tapeworm. At first nausea, vomiting, and diarrhoea were the only symptoms, but portions of tænia were shortly expelled, and the malady continued during five years without intermission. She was then admitted into the Hôpital Dieu, and submitted to a treatment which she cannot describe, but which succeeded in causing the expulsion of a large quantity of tænia, and delivered her during three years from all further annoyance. The cure appeared firmly established; the tænia returned, however, and since seven years the patient had tried numerous methods of treatment without any success. The characters of the worm having been well ascertained, in the exhibition of a dose of castor oil, M. Rayer prescribed seventy-two drops of the ethereal oil of mule fern, to be made up into twelve pills, six of which were taken in the morning and six in the evening—two hours after the exhibition of the last pill. Sixes of castor oil was given to the patient, who expelled in numerous fragments sixty-six centimètres of tænia. The accidents have since completely ceased, and no return of the parasite in the motions has been noticed.

M. Rayer prefers the oil of fern to the decoction of the fresh root of wild grenadier, which expels, it is true, with almost perfect certainty, the tænia, but produces symptoms resembling those resulting from the absorption of poisonous substances of an irritating nature.

D. MCCARTHY, D.M.P.

Pericarditis and Mercury.—Dr. Latham says, in English practice mercury is given from first to last, but it is for a time as if it were not given at all, for it produces no sensible effect. Common antiphlogistic remedies, however, are able again and again to mitigate and subdue symptoms; and so, at the end of a week or ten days, the patients are still alive, yet they are ready to die; but in a great majority of cases they do not die. Salivation arrives late, and seems to save them.

Engorgement of the Uterus with Hemorrhage.—The mouth of the womb, says Dr. Meigs, in his translation of Clobert de l'Isère's work, is enlarged in proportion to the engorgement, and this, as well as the whole surface of the tumour is the seat of a sanguine exudation, which, though often considerable and permanent, does not at all diminish the congestion. If the parts are explored by means of the touch and speculum the neck is found to be tumefied, softened, and of a more or less deep colour. The os, covered with clotted blood, appears smooth to view, but somewhat uneven to the touch; by gentle pressure a slight sensation of crepitation is perceived and an oozing of black blood produced, which escapes as from a sponge. When the disease has reached its last stage, the skin assumes a yellowish-straw tint; the eyes seem dull; and, in some women are observed to retain a certain degree of wonted robustness, it is because the surface of their bodies has become the seat of a general bloating, which conceals the wasting of their muscles. On examination per vaginam the neck of the uterus is found to be macerated and transformed into a sort of ulcer, presenting a layer which is softened and putrid, surrounded by a hard and, as it were, scirrhous tissue. Hemorrhagic engorgement which has reached this stage is extremely serious, and there is no hope of seeing tissues, so profoundly changed return to their normal condition. In general, the danger of the disease is in proportion to the violence and duration of the uterine hemorrhage.

Tubercular Disease of the Peritonæum.—Mr. J. Elkington presented lately to the Birmingham Pathological Society, the stomach of a woman sixty-five years of age, who had died of this disease. It appears to have existed for about six years. She suffered from violent spasmodic pain in the side, sometimes the right, and at other times the left, on the slightest exertion or on taking certain articles of food; a sensation of pain after eating, and sometimes vomiting violent palpitations of the heart, constipation and depression of spirits. The countenance exhibited great anxiety; tongue coated with

leop white fur in the centre, brown at the edges, and tremulous; pulse 100, small and compressible. There was pain over the whole of the stomach, but no tumor could be discovered.

The treatment consisted in the application of leeches; after their removal a blister, a saline mixture every four hours, with two pills, composed of pil. hyd., ext. colocynth, and hyoscyamus, at bedtime. Under this treatment the pain over the stomach became much diminished; tonics were then given, and she departed to a distance, and was lost sight of for some months. Three days before her death Mr. Elkington found her with suppression of urine, distended abdomen, and vomiting fetid matter. On the post-mortem examination a gallon of fluid was found between the layers of omentum. The stomach appeared contracted to the size of a closed fist, and was overlapped by the liver; it was hard on its external surface; both anteriorly and posteriorly were large deposits of a pinkish colour, one in particular posteriorly, and nearly the size of a nut, which had quite a calcareous appearance. The peritonæum in the upper part of the abdomen was healthy; the pelvic portion contained the pinkish deposits, easily recognised after being washed with water.

Mania.—A lady, thirty-one years of age, came under the care of Mr. Hay, of Sheffield, in consequence of an attack of mania, which appeared to be the result of anxiety and distress. All the functions were healthy. Blisters were applied, and tartar emetic used both externally and internally, and in four days produced the most beneficial effects. The patient has since continued perfectly well.

The Diarrhoea of Infants.—Dr. West concludes, from post-mortem investigations, that the diarrhoea of early childhood is at first merely an excessive secretion, and not the result of any appreciable morbid change; and that the anatomical alterations of the digestive canal are the consequences of the diarrhoea, not its cause, whence it happens that their extent is usually proportionate to the severity and continuance of the flux.

Constipation in Young Persons.—Dr. Dick considers this rather a sign of health than disease, arising from too great dryness and solidification of the fecal matters, and are thus reduced to so small a volume as not sufficiently to excite peristaltic action. This form of constipation usually disappears spontaneously at that time of life when, less exercise being taken and the development of the body being completed, absorption goes on less actively in the bowels, the mucous surface of which is again plentifully lubricated with mucus, as in the first years. The cure at the outset ought to be sought alone by attention to diet. The food should be pultaceous and herbaceous. This failing, injections of tepid water of considerable volume should be employed. If this is insufficient, a medicated one should be had recourse to, consisting of gruel, with olive or castor oil, or turpentine, or infusion of senna. If some aperient appears indispensable, aloes combined with myrrh, galbanum, or sulphur, fulfil the object intended. Castor or olive oil are perhaps the next best remedies. If the constipation of youth be not mismanaged, it generally ceases from the twentieth to the twenty-sixth year.

Mode of Administering Aperients to Children.—Phosphate of soda may be used conveniently as a condiment in soup in the place of common salt. Children may be unconsciously beguiled into the taking of the medicine in this way, and it will be found an excellent purgative.

Carminatives and Tonics.—Cullen's opinion was that coriander-seeds correct better than any other carminative the griping effects of senna. Cascarella, says Dr. Dick, is an excellent aromatic tonic, which agrees with most stomachs. It may be either given by itself, or else conjoined to stronger tonics or purgatives. Thus it corrects the cold and griping tendency of senna and neutral salts. In a course of tonics we may often advantageously commence with cascarella, and go on to gentian and quinine.

Mode of Detecting Morphia in Cases of Poisoning.

—M. Mermu's method is to wash with water, slightly acidulated with acetic acid, the solid matter ejected from the stomach. The product of the several washings is to be mixed with any liquids which can be collected. If one has liquids only at disposal, these are to be mixed with the water acidulated as above. The resulting mixture is then to be heated, and afterwards filtered; the residue to be evaporated to dryness, and treated with boiling alcohol, to separate the animal matter. To the filtered alcoholic liquid tincture of galls is to be added, made of 125 parts of alcohol with 250 of coarsely powdered galls; the whole to digest fifteen days, which will precipitate the little animal matter dissolved by the spirit, and the combination of tannin and morphia will remain in solution. The liquid mixed with a little distilled water is then to be filtered, and a solution of gelatine added in excess to decompose the tannate of morphia. The morphia then unites to the gelatine, while the tannin is dissolved in the spirit. To separate the precipitate it is necessary again to filter, and when the alcohol is evaporated the morphia will be left.

Hydatids of the Lower Lip.—Dr. Heller, of Stuttgart, has seen five cases in which accephalocysts were developed in the lower lip, and always on its inside. This affection appears first as a small and hard lump, which rapidly increases, so that in one month it may attain the size of a cherry; it gives rise to pain, deformity, and difficulty in moving the lip. The hydatids are seated immediately beneath the mucous membrane, and are transient. If they can be removed without opening their cavity, they are found to be made up of a rounded vesicle, full of fluid, transparent as water, and with a diaphanous and tender wall. The only cure consists in extirpating the cyst, which must be total, or it will reappear; hence nitrate of silver may be applied after the operation.

[In a case which came under our own notice about six months ago, in a young, delicate lady, seventeen years of age, the hydatid, situated on the internal part of the lower lip, had, in the space of three months, acquired the size of a small hazel-nut. We touched it with tincture of iodine once, twice, or thrice a day, as the patient could bear it, and in three weeks the transparent sac entirely disappeared, leaving a small ulcer with a hardened base; to this we applied occasionally nitrate of silver, which healed the wound. Gentle external friction twice a day, with a little iodine ointment, eventually removed every vestige of hardness.—Ed. Medical Times.]

Simple Encysted Growths.—Dr. J. H. Bennett describes these as formed of a cyst, composed of fibrous tissue lined by a smooth membrane. Sometimes the membrane is structureless, or only composed of areolar tissue; at other times it is lined with a distinct layer of epithelial cells, the nuclei of which are very apparent on the addition of acetic acid. The former kind constitutes the vesicles, so frequently found in the plexus choroides, kidneys, ovaries, &c., varying in size from a pin's head to that of a hazel-nut, or even walnut, usually with aqueous contents. The latter kind constitute the cystic growths arising in the follicles of the skin, in the mammae, ovaries, testicles, &c., which frequently reach the size of an orange, are sometimes much larger, and vary greatly as to the nature of their contents. For the most part they are sparingly supplied with bloodvessels, and seldom cause inconvenience, except from the deformity they occasion when situated externally.

Compound Encysted Growths.—These are of two kinds. The external sac may contain on its internal surface secondary or even tertiary cysts, which may be sessile or pedunculated, or the growth may be divided into numerous departments by divisions of the fibrous sac. This is the true multilocular encysted tumour. The external cyst in all these cases is formed of fibrous tissue. The internal surface is smooth, sometimes with, at others without, an epithelial layer. The primary as well as the enclosed cysts are, for the most part, richly supplied with

ble vessels, and hence they are peculiarly prone to certain exudation which has undergone various kinds of development, as well as to ulcerate. These growths frequently attain an enormous size, measuring several feet in circumference, whilst their internal membrane may secrete more or less rapidly gallons of fluid.

Popliteal aneurism usually easily treated by Compression—Mr Jolley, one of the surgeons to the Tisbury Dispensary, received under his care a tailor, thirty-six years of age, on account of popliteal aneurism. It had existed for a year, and for a fortnight before Mr Jolley saw him he was confined to his bed. The tumour occupied the whole of the popliteal space, and the limb was much reduced in size. On the 16th of February, firm compression was made on the tumour, which was gradually increased to the 20th, when pulsation was less perceptible, the pressure disturbed his rest, and the leg was very oedematous. On the 21st the tumour burst, and he lost a pint of blood; it was stopped by pressure. On the 1st of March a ligature was applied to the femoral artery, without loss of blood. The aneurismal tumour was punctured, on the 3rd there was a free discharge of fetid pus. On the 8th the foot and leg had become gangrenous, and it was deemed necessary to perform amputation.

Diagnostic Sign of Intercular Absorption of the Peritoneum—Dr Seymour remarks vomiting of a peculiar matter at a given season, that it is only to be compared with that which the sea acquires at a certain depth, a blue or intense green, is that of indigo deep green when regarded in one way, blue in another, as diagnostic of tubercular absorption of the peritoneum. Dr. Seymour says this disease is generally confounded with mesenteric disease, but that it is much more frequent—in the ratio according to his experience, of five to one. This disease he considers is not absolutely incurable, while he considers iodine to be the remedy on which the chief reliance is to be placed. Mercurials are considered to be injurious.

Concretion in the Appendix Vermiformis of an Infant—Professor Holmes of Montreal relates the case of a child, two years old, large and healthy, which had been ill disposed for a week with tenesmus, and inclination to run on long, it stool. On the eighth day the face became suddenly pale, the skin cold, and the pulse nearly extinct; he sank rapidly, without loss of consciousness, and in a few hours expired. On dissection, on raising the small intestines, all the portions in contact with the cecum were seen to be in a state of intense inflammation, in parts nearly black from extreme congestion. The appendix vermiformis was in its natural situation and scarcely changed in colour, but on the left side a small portion was softened and broken down exhibiting a rupture, the side of which were quite dilated. In the appendix a small concretion, about the size of a small pea, and two teeth broad, was found, pushing up its calibre. It was of a white colour as if calcareous, and pretty firm though crushed without difficulty between the finger and thumb. No feculent matter could be detected as having escaped and the concretion lay between the perforation and the natural aperture of the appendix. A fortnight previous to being taken ill the child had had several fits of violent vomiting, of which no cause could be discovered at the time.

Therapeutic Remedies in Tetanus—Dr J. Kubik says that the use of calomel, nitrate of silver, and tartaric acid, and of the copious, pale, and albuminous urine, with steady regulation of the pulse. Blood-letting is unnecessary, on the contrary, with a sensitive nervous system, and aching in the lumbar region, renders the employment of oily and emollient remedies necessary.

Dislocation of the Hip-joint—A servant girl, twenty years of age, sustained a dislocation of the hip-joint from a fall from the head of the bone being on the dorsum of the ilium. Three days after the injury the patient was first seen by the surgeon, and the following method used for its reduction.

After bleeding, and giving nauseating doses of antimony the patient was laid on her back on a low table, so that the feet were projected over the end of the table, the foot supported on a stool, and the left held by an assistant. A strong sheet was placed between the legs as a point d'appui, and brought round the pelvis was given to another assistant to produce counter-extension. A second sheet was passed over the upper part of the abdomen and the pelvis, the ends of which were held by two more assistants, so as to keep the patient firmly down on the table. Lastly, another sheet was passed round the upper part of the thigh, by which a fifth assistant was forcibly to draw the upper end of the bone outwards. The surgeon now taking hold of the limb, and bending it as much as possible to a right angle with the body, stooping down, placed the limb over his left shoulder, so that the lower part of the limb hung over his back. Fixing the limb in this position, and forcibly raising himself to the erect position forcible abduction being at the same time made by the hand placed around the upper part of the thigh, the head of the bone was at once made to resume its place in the acetabulum.

ROYAL MEDICAL AND SURGICAL SOCIETY.

CASE OF CYANOSIS, WITH A DESCRIPTION OF THE APPEARANCES PRESENTED ON DISSECTION.

By F. Le Gros Clark.

Assistant Surgeon to St. Thomas's Hospital, and one of the Secretaries of the Society.

W. B., aged nineteen, shoemaker, was admitted into St. Thomas's Hospital in July, 1846. He was of spare make, and his complexion was remarkably livid, skin cold and dry, lips swollen and blue, he suffered from urgent cough and extreme dyspnoea, especially in the recumbent posture, the superficial veins of the neck were distended and there was, at times, a jugular pulsation, pulse quick and laboured, the impulse of the heart was natural, but its sounds were superseded by a very loud, prolonged, systolic bruit, heard over the whole region of the heart, but most especially over the aortic valves; the sound, however, did not extend beyond its arch, in the direction of the aorta, but spread out laterally from the point where it is heard in its greatest intensity, with an equal degree of force along the course of the left branch of the pulmonary artery, to the periphery of the chest. The sound was also heard on the right side, but to a more limited extent; there was, also, a systolic bruit over the apex of the heart. These symptoms were unrelieved by treatment, and he died on January 7th, 1847. *Autopsy*—The liver was large and dense, the spleen was three times its ordinary bulk, but apparently unaltered in texture, the lungs presented tubercles at different parts, the heart was large, the left side presented no abnormal appearance of consequence, but the right ventricle (especially its appendix) was much dilated, and there was an oblique communication between the ventricle and the walls of the right ventricle were much hypertrophied, being nearly twice as thick as those of the left, and the cavity itself was slightly encroached upon. In place of the usual atrial outlet from this ventricle, there was a contracted circular aperture, about the diameter of a writing quill, which communicated with a small muscular chamber or compartment between the ventricle and pulmonary artery—the long axis of the ventricle itself being curtailed to a corresponding extent. Above this aperture there was a second outlet from the ventricle, of similar form and size, which opened into the angular interval between two of the aortic semilunar valves. The canalus arteriosus was shut, and closed by what appeared like a patch of organized lymph in the pulmonary artery. The bronchial arteries were unusually large and tortuous, as was also the arterial system generally, which terminated in the lung. The author remarks that the symptoms during

life were satisfactorily accounted for by the post-mortem appearances—the dilatation of the right auricle and hypertrophy of the corresponding ventricle being dependent on the obstructed atrial outlet from the latter. The morbid condition of the liver and spleen he considered as probably indicative of some function performed by these organs vicariously of the lungs, and that the large size of the bronchial arteries was due to the exigencies of the lungs, dependent on the obstruction of the circulation through the pulmonary system of vessels.

CASE OF ENCEPHALOID DISEASE OF THE BRAIN INDUCING AMBLYOPIA.

By J. Dalrymple, Esq.

Surgeon to the Moorfields Ophthalmic Hospital.

Miss B., about twenty-eight years of age, had been totally blind about four years, but the ocular symptoms date nearly a twelvemonth previous, commencing with dimness of vision in one eye, and gradually involving both in total darkness. There were no morbid appearances in either eye, and, with the exception of the iris being sluggish, there was little to indicate the extent to which the blindness had proceeded, for the pupils were never much dilated, and never wholly lost the power of contraction. About the time Mr Dalrymple first saw the case, there were obscure symptoms of some disease of the brain, severe pains at the back of the head, some partial numbness of one side of the face, and occasional jerking of the muscles of the right arm and leg. These symptoms entirely disappeared under a full course of mercury, and never returned in any noticeable degree. The blindness, however, continued. By careful dietetic and hygienic treatment, Miss B. enjoyed good health, only complaining of occasional vertigo, and subject to frequent attacks of "faintness," which occurred at irregular intervals, and lasted but for a few minutes. In the first week of February 1847 this lady died suddenly, with little or no premonitory symptom of illness. On examination of the body the day after death, a large encephaloid tumour was found at the base of the brain involving the chiasm of the optic nerves, and extending back as far as the pons Varolii; it then entered the middle lobe of the brain as high as the level of the lateral ventricle, on the right side which it compressed and nearly obliterated. The left side of the brain was healthy. The third nerve on the right side passed through the tumour, and the fifth nerve on that side was partially overlapped by it. No other nerve suffered by its pressure. This lady had an attack of measles three years previous to the development of any ocular symptoms. This attack was very severe, accompanied by delirium, strabismus, and dimness of vision, and although it was supposed she had entirely recovered from this illness, the author of this paper surmises the origin of the encephaloid disease may be referred to the cerebral inflammation which occurred at that time.

A CASE OF TETANUS FOLLOWING A LACERATED WOUND OF THE CORNEA, WITH A TABLE OF CASES OF TETANUS WHICH HAVE OCCURRED IN ST. GEORGE'S HOSPITAL SINCE JANUARY, 1841.

By George Pollock, F.R.C.S.

J. S., aged thirty-three, was admitted into St. George's Hospital, under Mr. Keate, on the 10th of January, 1847. He had that morning received a cut from a gig-whip on the left eye, which lacerated the cornea, dividing it through its entire thickness, and extending obliquely across from one margin nearly to the other. The aqueous humor had escaped, but there was no prolapsus iridis, and but little pain or chemosis. Goulard's lotion was applied, and an antimonial and aperient saline ordered every six hours. On the following day the lids were distended and tense, and there was great chemosis, the conjunctiva almost hiding the cornea, the pain also was great in the globe and forehead. Six leeches were ordered to the left temple, and warm fomentation. The above symptoms were still further aggravated on the following day, when several punctures were made in the upper lid, which afforded immediate relief. On the third day,

the leeches were repeated, and three grains of calomel and half a grain of opium were ordered twice in the day. On the sixth day, the visible portion of the cornea was cloudy, and on the seventh there was purulent discharge from the tense and projecting globe. On the evening of the same day, the muscles of the face on the right side appeared contracted, and the patient complained of stiffness about the jaws. On the ninth day, trismus was fully established, and the hemiplegic condition of the face had become more distinct. He had been blistered and cupped on the previous day. A puncture was made into the projecting globe, and gave exit to some foul pus. General tetanic symptoms subsequently supervened, and he died on the following morning, an ineffectual attempt having been made to affect him with the vapour of ether. On examining the body, the vessels within the cranium seemed to be congested, as were those of the mucous membrane lining the larynx and pharynx. The liver and kidneys were also gorged with blood. The globe of the affected eye was completely disorganized, its different component structures being so closely at all distinguishable. The author considers the above case interesting from its extreme rarity, as he is unaware of any record existing of a similar lesion producing corresponding results. The apparent paralysis of the face he also regards as an interesting complication, and it was unexplained by the *post mortem* examination. The irritation and distress occasioned by the attempt to administer the vapour of ether were such as to forbid perseverance in this endeavour to relieve the patient's frightful sufferings. In the tabular view which the author gives of ten other cases of tetanus admitted into St. George's Hospital since 1811, it appears that only two recovered. Seven of the fatal cases were traumatic, and the symptoms of the disease declared themselves within three weeks of the receipt of the injury, with one exception. In four cases the brain was rather congested and in one there was softening of the spinal cord. The author remarks, that no satisfactory conclusions can be drawn from the treatment of these cases, both opium and India-rubber having proved uncertain and unsatisfactory remedies.

MEDICAL SOCIETY OF LONDON.

Dr. Marshall Hall read a paper on the Convulsive Affections of Infants and Children.

The author began by alluding to the dangers attendant on infantile convulsion, to its consequences to mind, limb, and life, and to the possibility of idiocy, or liability to epilepsy, being its result. He then made reference to the causes, forms, and effects of such convulsions and the mode by which they are induced, and then proceeded more particularly to consider them. He dwelt especially on

1. *The terms employed to designate certain forms and symptoms of them*, and on one especially, laryngismus stridulus, which the author contended was no more a disease than cough was a disease, or "any other symptom of disease was a distinct disease." He said, that laryngismus was not always stridulous, but depended on the same causes, whether it was or was not so, the most dangerous forms of it were those which were noiseless. He would associate this symptom, which was certainly one of great peculiarity and danger often, with contraction of the hand, which he would call *chirismus*, and with that of the foot, which he would style *podismus*, the term *sphincterismus*, too, might be applied to spasm of the sphincter ani, or neck of the bladder. "Let the termination in *ismus* be used only to designate a symptom and that of a purely nervous or convulsive character."

2. *The predisposition to convulsive affections*, and laryngismus muc especially, was very marked. The latter had been known to affect a whole family. The cause of such predisposition was obscure: was it hereditary? was it the effect of locality, or emanations from the soil?

3. *The causes*.—No irritation of the cerebrum or cerebellum could immediately produce muscular spasm, as experience had shown again and again. But irritation of the membranes of the brain might excite it, as appeared from an experiment which he had performed, and recently detailed. Irritation of the medulla oblongata, or medulla spinalis, produced the most frightful spasms. The incident nerves, when affected at their origin in the cutaneous, mucous, or other tissues, were the most frequent source of the attacks. The condition of the gums in teething, gastric, or intestinal disorder, matters retained in the lower part of the alimentary canal, the atmosphere itself, especially when north, east, or north-east winds prevailed, perhaps certain vapours, these were all insisted on as being intimately connected with the production of convulsion or that form of it called laryngismus. Strabismus, or the spasmodic condition of the hand or foot, might arise from teething, &c., but the larynx was very apt to be affected by the north-east winds, or other conditions of the atmosphere. He also associated laryngismus stridulus with undue excitability of the spinal centre, when it seemed to rid of, it was very apt to recur. Hence the precaution of persevering with remedies longer than would otherwise be necessary.

4. *The influence of Sleep*.—He alluded to the frequent occurrence of convulsions at this period, chiefly epilepsy. There was congestion of the nervous centres then, probably unusual excitability of them. Altogether it produced a state favourable to convulsive seizures.

5. *Cerebral Diseases*.—On this the author forcibly insisted. He referred to the consequences of inflammation, tubercular granulation or tumour, and effusion at the base of the brain, and also to the congestion of puerperia.

6. *Excited Reflex Actions*.—By far the greater number of convulsions was of a reflex nature. Laryngismus was in so effectively avoided by removing every exciting cause of reflex action. He would chiefly guard against four causes of such action. First, irritation of the trifacial nerve, which took place in teething, second, that of the pneumogastric nerve third, irritation of the spinal nerves, and fourth the effects of the atmosphere upon the larynx, under certain circumstances. The organs affected in a convulsive seizure were precisely those which its pathology would lead us to expect, the larynx the sphincters, &c. The author then called the attention of the society to certain bronchitic, hepatic, and renal symptoms, and to the condition of the urine, points which needed further investigation. He then dwelt on the effects of—

7. *Intoxication*, passive and showed how great and important was the part which they played in the affections he was treating of. He insisted on the necessity of bringing them in mind fully in certain cases, he showed that they often constituted the ail and only objection to the use of the gum lancet, which consequently should always be cautiously employed.

8. The effects of unmoderated excitability were insisted on. States of the nervous system, induced by mild electricity were compared with those occasioned by disease. The results of increase of excitability were entered into irritants then acted, which at other times would be inert. A change in the direction of the wind, even, was not without bad consequences. Strychnia induced a species of laryngismus. Motion, hysteria, epilepsy, tetanus, hydrophobia, all affected the larynx in a peculiar manner.

The author next described those affections of the cerebrum which were consequent on convulsions, the congestion, the effusion, the occasional paralysis, the risk of idiocy, &c. He then passed on to the question of sudden dissolution, demonstrating how difficult it was to foresee it often, and stating how frequently it happened when the patient appeared in progress to recovery. It was the result of common asphyxia, but not rarely of what he had called secondary asphyxia, which he believed was closely dependent on the blood of the coronary arteries

being unduly arterialized. The result of asphyxia should be enforced promptly in such cases of sudden death.

Some observations were then made on the diagnosis of convulsions, in which the transient, or permanent, or complicated character of symptoms, as the case might be, were all pointed out as modes of assistance in conducting the inquiry. The author drew attention to the *post-mortem* appearances, which varied as the disease was centric or eccentric, or according to the mode of death. There might be the results of inflammation within the cranium, or nothing found whatever but the appearances proper to asphyxia. Lastly, he made some practical observations upon prevention and treatment, as to the latter, insisting on an accurate diagnosis as an indispensable preliminary, on a due attention to the complications of the affection, on the necessity of bearing in mind all the varied forms of irritation, and applying the appropriate remedies without delay, on having regard to the state of the patient during the time of sleep, on protecting it from cold air, &c. And, if he had shown the application of the physiology of the nervous system to its pathology, he had gained the object which he had in view in bringing the subject before the society.

REVIEWS.

Observations on the Treatment of Lateral Curvature of the Spine, pointing out the Advantages to be gained by placing the Body in a Position to produce Lateral Flexion of the Vertebral Column, combined with the After Application of firm Mechanic Support. With woodcuts. By EDWARD L. IONSDALE, Fellow of the Royal College of Surgeons, &c. London.

John Churchill, Princes-street, Soho, pp. 116.

The subdivision of labour in the profession has its advantage, when an individual directs his attention to some particular department of medicine or surgery, having studied the science closely as a whole. Nor is it without its disadvantages, as in pure surgery, where there must be an almost irresistible temptation to the use of the knife in certain accidents and diseases, that the operator may show his dexterity and save himself much after trouble. The particular department to which Mr. Ionsdale has directed his attention offers no temptation of this kind, and, as it is one where a knowledge of mechanics as well as therapeutics is especially requisite, is very proper for special study. It is truly lamentable to contemplate the number of victims, interesting in account of their sex and age, whose health and beauty are sacrificed to that all-powertful duty fashion. The education of young females is begun, continued, and ended in accordance with certain established usages, which, instead of producing elegance of figure and gracefulness of action, too frequently lay the foundation of disease or deformity. An "establishment for young ladies" has long been fixed and immutable as those of the Medici and Perissini, and to infringe one is little short of an unpardonable sin. It is no wonder, therefore, what with discipline at school and at home, sedentary occupations, cramped positions, and tight lacing, that very many young females of the middle and upper classes should become the subjects of that peculiar deformity for which it is the object of Mr. Ionsdale in the present treatise to make known to the profession a mode of treatment he considers superior to those generally used, and which in his own practice has been eminently successful.

Our author observes that the "lateral curvature is almost always found to be on the right side, and classifies the principal causes under three heads.

"*Predisposing causes*, as general debility, producing weakness of the muscles and ligaments, the difference in strength showing itself more readily in the spine than other parts of the

Medicine.—If the chance of "THE SHADY BILL" becoming law depended on morals in it, or discernment in Parliament, we should say at once the profession may be quite at its ease. There can be no chance of its success. But, in the present state of parties, it depends on no such contingencies; and the only way to defeat it surely is to oppose it energetically. Our correspondent should forward his petition immediately.

Senex is quite accurate in his estimate; but his accuracy (not through his fault) is so fatal to its victim's character, that the unspeaking world would call it sourrility. We must, therefore, decline the letter.

M.D.—There can be doubt of the strength of the grounds on which we have applied for a new trial, and, though our correspondent's point has not escaped us, it was really not required for the success of our application. In Westminster Hall there is only one opinion on Judge Pollock's address to the jury.

A Student may graduate without any such preliminary.

A Rural Practitioner should apply to the Court of Queen's Bench for a mandamus. There is no doubt the coroner was in fault—as is, indeed, clearly established by Lord Denman's judgment against the West Middlesex coroner.

F. B. H.—Although the Apothecaries' Society have the means now in their hands of putting down all pretended apothecaries by a very summary and very efficient process—indictment for misdemeanour—it is only exercised by the society against notorious quacks. Our correspondent may, therefore, have no fears.

A Practitioner, who complains that if the new bill pass he will lose his privilege of not being tasked as a constable or juryman unless he consent to badge himself a "member" in the registration list, should petition forthwith against the bill.

Letters and communications have also been received from Mr. Edwin Morris, Mr. David Burns, Newport-Pagnell; Mr. Wm. Smith, Belper; Delta; T. J., Cleveland; Students, B. A., King's College; A Non-medical Reader, Manchester; Mr. L. Rich; Jacobus, Hildesheim; An Incautious Student, B. B. C., Bermondsey; A Country Apothecary; Philo, Dublin; Med. Baccalaureus, Medus, Dublin; Thomas N., Malmesbury; A Member of the National Institute; Mr. H. G. Delaunay, Gravelle, Havre de Grace; A Student of Downing College, Cambridge; F.R.S.; Mr. G. Hulford; A Friend and Old Subscriber, A General Practitioner, Zeta; Mr. Beale, a Surgeon, and Mr. Millett Davis, George-street, Liverpool.

THE MEDICAL TIMES.

SATURDAY, JUNE 12, 1847.

THE COLLEGE, THE COMPANY, AND REFORM.

THE profession has been lately edited with an account of two new discoveries, especially interesting to it:—by the one is shown how to make a surgeon in a very short time; by the other, an effectual method for the extirpation of quacks. The first process has been tried with unflinching success in the examining-room of Surgeons' College, and the other within the precincts of the Old Bailey. By the first, a pastry-cook has been dubbed a college member; and, by the second, a druggist has been compelled to don a medical title. These are significant discoveries, at a time when the general practitioners of this empire are seeking to procure such a measure of reform as shall confer upon them rights and privileges of which they have been long deprived, and which at the same time shall effectually check the growth of quackery. Like a deadly upas, this has taken root within the

sacred enclosures of medicine, and, under the fostering care of institutions ill adapted to the exigencies of the profession, it has shot forth from its wide-spreading branches twigs which, if suffered to fasten themselves in the soil, must eventually darken it with the shadow of death. Hitherto, neither the colleges nor the public have lent a helping hand to extirpate the growing evil—the one viewing it as a source of personal and corporate aggrandizement, the other charmed into a dangerous repose by the promising appearance of its foliage. The labour, therefore, of first cleansing, and then cultivating, the ground has devolved upon the "working class" of the profession—the general practitioners, and the eventual production of good fruit will be the reward of their arduous efforts.

The recent conduct of the College of Surgeons, and the construction which has been lately put on the penal clause of the Apothecaries' Act, will not fail to help the cause of reform; by showing its advocates not only the kind they need, but the advantageous position they occupy to enforce it. For two successive weeks we considered it our duty to advert on the conduct of the Court of Examiners in Lincoln's-middie, for granting a testimonial of fitness to practise surgery to an individual who had only studied one year in a medical school. This is one of the most convincing proofs, if more were wanting than the profession already have, that the council care not who is let loose on the public, or with what title to practise, so that they may have a good dividend arising out of diploma fees. The Taunton homeopathist did not wend his way to Apothecaries' Hall, in Water-lane, with the hope of obtaining their certificate: there the funking-room was dreaded more by far than the aristocratical visage of Sir Benjamin Brodie, or the piercing eye of Orator William Lawrence. The chink of the sovereigns was known to be all-powerful in relaxing the features of the one into the blandness of affability, and the stern glance of the other into the smile of benignity; while the examiners of the plebeian company, with their six-guinea certificate, required something more than the gold to make them propitious. Now, we ask if any measure of reform, short of one which will strike at the root of the corruptions in the College, will do for the profession? As it is now constituted, it is a disgrace to the medical institutions of the country, and throughout its whole career it has barely endeavoured to keep its members from the enjoyment of corporate privileges, and to bring them under a yoke, that a favoured few may place their feet upon their necks in their ascent to seats of honour. A registration bill will no more remedy these evils than the book which is annually published of the members' names, while it will double the chains of slavery, by perpetuating corporate distinctions. The education clause is merely a gilded bait to catch fools: for, while it allows a practical examination for the diploma, it does not enforce one; and it will permit the mammon-loving council to indulge their propensities in spite of all the remonstrances of an indignant profession. Never can any substantial good be enjoyed till there be a thorough change in the administration of the affairs of medical corporations; or till a college be established whose officers shall be responsible to the members at large, and who shall hold for limited periods their sacred trust. The great object of a change we conceive to be to secure an honourable position for the general practitioner; to remove every real cause of dis-

content; and, by granting to each those privileges which justly belong to him, to unite in one harmonious whole the different orders of the medical commonwealth. While we should think that the recent disreputable conduct of the College authorities has opened the eyes of all to the necessity of reform, and to the law that is required, the recent trials and convictions under the Apothecaries' Act for illegal practice should teach the general practitioners that, with so good a barrier against aggressions from without, it may also prove a most efficient help to reform within. It is now established beyond all doubt that there is the power to inflict summary punishment on those who without authority, or for pecuniary reward, administer medicine to the sick. The Society in Blackfriars are possessors of this law, and they hold it in trust for their licentiates, the greater part of whom possess a double qualification; and it can only be resigned by the majority of the profession demanding the same. We are no advocates for the Company continuing a medical licensing body, though we are bound to say that it has not only checked the rampant exercise of power in the authorities of the College of Surgeons, but has forced them to raise the standard of qualification of candidates for the diploma. A trading company, however, is not a corporation suitable for the government of a learned profession, nor is the position in which their licentiates stand to them a whit better than the members of the College of Surgeons to their institution; yet we must give honour to the Apothecaries for their efforts on behalf of medical education. They have raised it vastly superior to what it was when they obtained their act in 1815; and they have always manifested solicitude for the welfare and efficiency of those over whose interests they preside. Even Mr. T. Wakley, who in bygone days put them into petticoats and mounted them on broomsticks, as the "old hags of Rhubarb Hall," has appeared to exercise a friendly feeling towards them in his Medical Registration Bill, for he would still permit them to grant certificates to practise without the trouble of prosecuting offenders. The Company, however, has declared its willingness to forego these privileges on condition that a charter of incorporation be granted to a new college, in the management of whose affairs the general practitioner shall have a voice. This is the grand foundation of sound Medical Reform, and for which he must laboriously work, and patiently wait, till it is firmly laid. The "penal clause," retained with tenacity by its present possessors, till this is accomplished, will hasten its consummation. The value of this portion of the Apothecaries' Act is well understood by those medico-political tinkers who would use it with some "soft under" to bottom the saucepan originally manufactured by Sir James Graham, but purloined from him by Mr. Wakley. The "old ladies," however, are too sharp-sighted to allow the propensity of appropriation to be exercised by the honourable member for Finsbury without a check; and if he hopes to complete his work at their expense he will find himself sadly deceived.

Registration offers no high boon to the profession which it does not already possess, and it is certainly a thing of subordinate importance compared with the efficient organization of medical men. Already are they enrolled in the books of the different institutions to which they belong, and it is the height of folly to imagine that an act of Parliament to enforce registration would

at the same time check the bold pretensions of ignorant quacks. Moreover, the passing of such a measure would have the injurious effect of postponing to a far distant time the settlement of those differences which unhappily prevail so much in the profession. Recent events have taught it an important lesson that organization and incorporation are the only means to preserve and to maintain respectability, and, this being accomplished, it will be no longer desirable that the Apothecaries' Company should retain the power of licensing practitioners in medicine, or of punishing those who unlawfully assume their

high thereto (in wanting) to that infamous injustice to the surgeons of this empire—the recent surgical charter, that charter which without such confirmation, is legally null and void.

(It leaves the vast body of medical practitioners in an infinitely worse position than they have ever before occupied. It leaves them unprotected, for it virtually annihilates the act of 1813, it will introduce to their level a new horde of semi-educated young men, who will be admitted to universal practice on one qualification, and that a low one, and it finally excludes them from that charter of incorporation which can alone set right past indignities, and give efficient security for the future. What had the general practitioners done to merit so malevolent a project for their ruin? Is this to be the penalty of their independence? Thus the punishment of their universal excommunication of the bill's author? We will not pretend to say, but this we will affirm, that they will deserve all that is meditated against them, if they do not address Parliament as one man, and without in any way delay, against this most iniquitous of English projects.

A WORD TO THE PROFESSION

We cannot urge too strongly upon our readers the propriety of immediately petitioning against Wakley's Registration Bill—so called, but in fact, a bill to degrade and destroy the general practitioners of this country. Registration, justly accomplished is undoubtedly a good thing, but its concomitants in this bill are vicious and disastrous in the extreme.

A strong reaction against this measure is now going forward in the provinces, the members of the profession at Southampton have almost to a man petitioned against it, and in another column we have printed a copy of a petition from Liverpool, signed by nearly all the general practitioners around that neighbourhood. Other petitions are in process. A great number of gentlemen in the Tower Hamlets have forwarded petitions to the House against the bill, and there is a general sensation in the metropolis in condemnation of the measure. The eyes of the profession are gradually opening to the extent of the evil which this bill would inflict if it should become law, and the opposition to it is likely to be very active and general.

The profession are under obligations to our correspondent, 'Vox Veritatis,' who has ably demonstrated the injurious tendencies of the bill, and we trust that the profession will speedily and powerfully act upon his suggestions, and petition, from one end of the country to the other, against so dangerous a measure. It is particularly important that petitions should be forwarded *immediately*, while the special committee is sitting. Individual petitions will be as effectual as others. Numbers are wanted.

The Special Committee to which we have alluded appears to be entirely under the thumb of Mr. Wakley, who has contrived that its meetings will be held with closed doors. No fact could more clearly demonstrate this individual's conviction of the injustice of his bill, or his dread of an honest inquiry into its merits, and of his resolution to carry it into effect by every dirty manoeuvre and back-street game. Why should this special committee be held in secret, rather than an open meeting, free to all the world? Mr. Warburton's committee was an open one, but

Mr. Warburton was an honest man. Herein lies the difference.

We have heard of certain other intriguing attempts of Mr. Wakley to bribe the inquiry, which in due time we will make known. The point is not yet ripe.

CIVIL RIGHTS v. CORPORATE RIGHTS.

TO THE GENERAL PRACTITIONERS OF MEDICINE, &c.

GENTLEMEN,—There are two factors in every question of civil polity; and it is just in the degree that we are enabled by judgment and experience to compare and weigh them, that we can arrive at a sound decision on any point subject to dispute. I should be doing no credit to myself, and a positive injustice to your good sense, if I attempted, by partial arguments and in a partisan spirit, to thrust my views upon your attention, and to require your assent to opinions and principles, which I might seem either unable or unwilling to establish by an honest, unbiased, and comprehensive survey of the elemental truths and the contingent relations that constitute the question respecting which my views and opinions may be urged.

I shall never cease, through the medium of a fearless press, to advocate the interests and independence of my class in the profession, but I shall also fulfil my duty, on necessary occasions, to recur to original principles in order to show that the opinions I enforce, and the policy I promote, are founded in justice and truth. If I can thus convince your mind of the immutable foundation on which my advocacy rests, my warmth of expression I may employ will not only be excused but justified. There is an undying and unreconcilable antagonism between truth and error. Truth admits of no compromise—her association with error is reluctant, the union is one of coercion, and cannot be, for any length of time, approved or maintained. It should be our business to resist the violation.

My object, gentlemen, in addressing these letters to you has chiefly been to induce you to stand fast by your original demand of a *Charter of Incorporation* for the general practitioners of medicine of this country. There is unfortunately such a variety of interests among the members of our profession, that it is exceedingly difficult, during any lengthened period, to direct their *unanimous* efforts to the attainment of any specific object. There is a want of that elevation of view, and freedom from personal bias, that alone can harmonize the conflicting forces, and conduct their exertions to a successful result. This is deeply to be lamented—it makes our labours trivial, our professional character contemptible, and our integrity suspected. A vicious and unprincipled press has, hitherto, assiduously fostered these elements of discord, and has found its interest in arraying them in practical hostility and factious retaliation. Nothing is so dishonouring to our profession, or can be more inimical to our true interests. Let us learn better, and act more wisely.

The great cry now vociferated in favour of this Medical Registration Bill, and often urged on my attention, is, that all individuals in the country have *equal civil rights*, and no corporation should be permitted to exercise a power that prohibits any qualified man from practising in any part of the kingdom. This is one factor of the question. The *civil rights* of each individual may be the same, as a member of society, the law that applies to one, applies, or ought to

"THE SHABBY BILL"

PARLIAMENT will be dissolved about July 15th—the SECRET COMMITTEE on Medical Reform will have finished its sittings in a few days, there is, therefore, yet time to smuggle "THE SHABBY BILL" through the House, if the profession do not immediately set itself in motion. Never were decision, promptitude—vigour more required. The author of "the shabby bill"—however great his intellectual indigence does not want adroitness, the members are now thinking of personal prospects is infinitely more important to them than anything so contemptible as this mischievous scheme of our only "medical representative." The Government is too occupied with self defence to venture on troublesome opposition, there is no chance, therefore, but in our own activity and energy. Let meetings be held in every district in which they are possible, and, where such combinations are inconvenient or impracticable, let each practitioner petition for himself. There must be no delay.

The defects of "THE SHABBY BILL" are as cardinal as the measure itself is petty.

1. It does not settle the great point of counter practice by druggists. On the contrary, it does much to encourage further encroachments, by throwing increased legal difficulties around a subject already too much surrounded with them.

2. It does nothing to secure representation in the medical government of the profession. The responsibility of which the profession has complained as the principal source of half our calamities remains just as it was. If anything be done it is to corroborate and confirm that irresponsibility.

3. Education is left just as it is—safe for deterioration. This is leaving all institutions to the highest it degrades them to the lowest level. In self defence there is no respectable institution in the country that must not shorten its *curricula* and lower its examinations, if the "shabby bill" become law. This will be the future candidate, the lecturer, the apothecary to cure every defect of an equivocal and disgraceful examination, and the student who will become involved in a labyrinth of worse ones in the race of low towns. Defective examinations.

4. It gives the Secretary of State power of interference in our concerns, which will ultimately be most troublesome and dangerous. It can be of no efficacy or utility. In fine, if you can, a more ridiculous proposition than that of the First Secretary of State of such an empire as ours, pretending to investigate and to judge upon summary and without regard to the relative merits practically, of medical education by Glasgow teachers in the north, or Metropolitan teachers in Lincoln's Inn.

5. It gives the sanction of Parliament (which

apply, to all, but it is a great mistake to imagine that civil rights, so called, can either ignore or confer professional rights. The only rights that are on principle inalienable are natural rights; these, in a state of civil society, are enjoyed under certain restrictions, the principle of these rights is immutable, but the mode and the extent to which they may be exercised are various as there are forms of civil government. Civil government also confers rights, but these rights affect the individual only in his relations to society and the state. In the same manner and for the same reason that civil government limits natural rights, so professional bodies are invested with powers to limit civil rights. Professional or corporate rights are the second factor of the question.

Civil rights and corporate rights are in mutual antagonism, and must be equally respected. If the doctrine of civil rights were carried out to its extreme limits, our profession would be annihilated as a licensed body, and a certain number of individuals would be licensed by the State to practice medicine in the same way that persons are now licensed to sell "pepper, tobacco, and snuff." This is the evil tendency of the Registration Bill. The medical question is regarded by its author simply in this point of view, and if his bill were to pass through the Legislature, no arrangement would exercise more direct influence in overthrowing our corporate organization, and abolishing us as a profession. Mr. Wakley is not a man of sufficient mind to embrace this question. Of an energetic temper and with a ready command of expedients, his intellectual powers are of a limited order, and are totally incapable of grasping a complicated question with that firmness and clearness which is necessary to a thorough understanding of its bearings and to form a decisive line of action for his life in fact. He is fully acquainted with all the details of the subject, but cannot comprehend it as a whole. Hence he is always the advocate of partial schemes, and the malignant critic of general measures. *He is a man of a low intellectual order. More cleverness is his characteristic.*

Gentlemen, the same principle of aggregation that prompts men to form themselves into civil communities, unites them also in corporations. Men feel that divided and isolated exertions avail little to the fulfilment of great public objects, and that power is always exercised most beneficially in combination. Hence associations are formed for the transaction of merely temporary purposes, or for the immediate accomplishment of final measures, when, however, the object is permanent, and requires a perpetual exercise of supervision and authority, either to work it out in fact or to maintain its efficiency, the association becomes a corporation, the transitory combination becomes a permanent establishment, and a part of the civil government of the empire.

Corporations are formed for two objects: the preservation of special interests, and the promotion of the public welfare. In early stages of society these two objects are considered practically incompatible—or, rather, the conservation of the special interests of the body is deemed the only end to be achieved, and the public good is regarded either as in antagonism to it, or is included in it. The public, in pursuance of their civil rights, insist upon the antagonism, the corporations, in defence of their privileges, retort that their independence secures the public welfare.

At the present period of society, gentlemen, clearer notions of these matters obtain. The public good is the great end of legislation in all its subdivisions. So far is the peculiar privilege of corporations in harmony with the interests of the public that they are founded in truth, and are impregnable by the violence of fiction or the vulgar outcries of aspiring selfishness.

Now, gentlemen, in our own case there can be no question that the interests of our profession are identified with the welfare of the public. The public's good is achieved by providing duly qualified medical attendants in all circumstances of accident or disease, and there can be no doubt that the welfare and respectability of the profession depend upon the educational attainment of its members. It is, then, the paramount duty of every medical corporation to provide for, and acquire, a high standard of qualification as the condition of membership.

How is this duty to be enforced, and the end attained? Corporations are essentially selfish, and seek the advancement of their special interests, and the more the circle of their interests is contracted the more selfish they become. This is a necessary evil of corporations, but it is an evil only when it counteracts the free and expansive operation of exterior agencies which are subservient to the public good. It is now the great and self-deceiving evil of our corporations. Their interests are too exclusive and override the general welfare they are injurious to the profession, and pernicious to the public, and they cannot be permitted to retain this invidious, hostile, and destructive supremacy. The remedy is that each class in the profession having at present separate interests shall have an *implied* control over its own standard of education. The time may come when the separate classes will admit that their interests are common, and then government should be one also. This principle is now in progress of fruition: it is not yet perfect, but will be perfected in the future.

Then, gentlemen, are the two factors of the question involved in the scheme of a general registration of the profession, and how are they to be reconciled? A large section of the profession, now protesting under the interdiction of laws and corporate privileges, plead their civil rights, though they should remember that the phrase, in this instance, is only a figure of speech; that civil rights are conferred by the laws, that corporate rights are in fact civil rights, and those who practice contrary to the statute have no civil right so to do. Nevertheless there is a principle of civil right, variously denominated justice, equality, &c., which throughout in all its phases embodied is a legal fact exercises so powerful an influence on the destinies and duties of society to be overlooked. And I am well content that this principle whose oracle is public opinion, shall assume to itself the character of a civil right.

Reason upon the subject gentlemen, in any manner and to any extent we may, we shall find that no measure of Medical Reform can be satisfactory that does not comprehend and reconcile these two principles. While we concede the civil rights of one section, we must secure the integrity and the honour of the whole body, and, through it, the public welfare. Any other proceeding is partial, quickish, and injurious. A low demagogue, an intriguing adventurer, or a malicious enemy, may affect to serve us by promulgating schemes that, being narrow and unsound in principle, can only set us at variance, but I trust that the respectable and well-

informed portion of the profession will visit such conduct with merited indignation and scorn.

The policy of the NATIONAL INSTITUTE offers a common ground for all honest reformers to unite and operate on for the attainment of their respective objects. It is the only policy that will bear inquiry—that is truly liberal, and therefore just and honourable. The gentlemen comprising this body are willing to grant equal rights to all qualified members of the profession, and at the same time seek to establish the profession on a sure, just, and comprehensive basis. They desire no exclusive privileges, on the contrary, they will admit all qualified practitioners, who may wish to join them, to all the rights and immunities they may acquire for themselves. Their policy is the only one that embraces both factors of this question, and resolves the dispute. In whatever light we may regard this subject, however we may turn it about, and examine it in its varied aspects, we are still driven to the same conclusion,—that an INCORPORATION of the general practitioners, embracing every qualified member of this branch of the profession, is wise, conciliatory, and truly liberal, and the only plan equal to the solution of the difficulties of the question, and to the satisfactory fulfilment of the various exigencies of the medical profession.

I have the honour to be, Gentlemen,

Yours, very faithfully,

VOX VERITATIS.

MISCELLANEOUS CORRESPONDENCE.

DR. BURRIANF ON THE OXIDE OF SILVER AS A REMEDIAL AGENT

My attention having been directed to a communication respecting the oxide of silver from Mr. Underwood which appeared in the *Pharmaceutical Times* of last week, I beg to offer a few remarks on the subject. I introduced the remedy to public notice nearly six years ago; and, having been constantly in the habit of using it and distributing it extensively, I have doubtless had as much experience in its preparation and compounding as most persons, but no mischance has ever befallen me or my patients from its explosive property, which, indeed, the genuine oxide of silver does not intrinsically possess. If, however, the substance be incorrectly prepared or injudiciously combined, I cannot guarantee against a chemical action occasioning explosion. On the contrary, such will infallibly be the case in some instances. The formula for preparing the oxide of silver which I recommend is as follows:—Dissolve four parts of the nitrate of silver* in distilled water; also rather more than two parts of the hydrate of potash in a separate quantity, freeing it by filtration from the oxide of iron and other impurities; mix and let stand for an hour, stirring frequently with a glass rod, the supernatant liquid will be found a solution of nitrate of potash, the freedom of which from nitrate of silver may be ascertained by taste, or by testing with hydrochloric acid, showing that complete decomposition has been effected, otherwise more solution of potash should be added, the fluid is then to be poured off, and the precipitated oxide of silver to be washed repeatedly with distilled water until it is found to remain perfectly clear and quite devoid of all taste and alkaline reaction. The precipitated oxide is then to be drained on filtering paper and thoroughly dried at a temperature of about 150° F. If preferred,

* The grey nitrate should be used, as I do not feel assured that the white variety is always a proto-salt.

the oxide of silver may be prepared *ab initio* from pure metallic silver itself.

Neither lime nor any other alkali will answer the purpose of decomposing the nitrate of silver as well as the potash; and the preparation with ammonia is dangerous in the highest degree, as well as objectionable on other accounts. When the oxide of silver is prepared as I have described, neither heat, friction, nor percussion will occasion any explosion. It may be combined with any vegetable extract or powder without any material decomposition ensuing; nor will it, I believe, be altered in its chemical nature by either starch or sugar. The conjunction of oxide of silver with confection of roses is injudicious, as a salt of silver is liable to be formed, though certainly the tendency of metallic oxides to be acted on by the vegetable acids (gallic, malic, or citric) varies much. The combination of essential oils with the oxide of silver is exceedingly objectionable, for the chemical union of the oxygen with the silver is not very powerful; neither is that of the hydrogen and carbon in the essential oils; the substance in question, therefore, being intimately commixed, silent or explosive combustion will inevitably ensue, the oxygen and hydrogen forming water, while the silver remains in a metallic state, or is converted into a carburet. An analogous, though more complicated, action, I think, takes place when the vegetable acids are concerned. I should not recommend any druggist to dispense a prescription wherein the oxide of silver and an essential oil are conjoined without communicating with the prescriber if possible.

The combinations of the oxide of silver which I chiefly employ and should recommend are as follows:—

1. With extract of gentian or camomile.
 2. With extract of hyo-cyanus or conium, to which I often add a small proportion of ipecac.
 3. With inspissated oxgall.
 4. With the aqueous extract of opium.
 5. With compound cinnamon powder.
- The pills should never be rolled or kept in carbonate of magnesia.

I trust that the insertion of these few remarks may attract the attention of the numerous readers of your valuable periodical, and be a means of preserving a valuable remedy from undeserved discredit.

MR. DERMOTT AND MR. BLAKE.

[To the Editor of the Medical Times.]

SIR,—Much has been lately said and written respecting the mode in which Mr. Blake obtained his diploma from the College of Surgeons; and as he attended the lectures delivered in the School of Medicine and Surgery to which I belong, and, moreover, as a point of honour, I must see justice rendered and truth stated concerning my pupils, I may, perhaps, claim the privilege of intruding a simple fact or two upon the columns of your justly popular journal.

It is a fact that Mr. Blake, during the whole of the time he was attending my school (twelve months), was unremitting in his studies, morning, noon, and night; in fact, no student could have exhibited a greater degree of application than he did.

He was constantly engaged in dissection, and I verily believe that he did not miss a single lecture or demonstration delivered by me during the whole of the above-mentioned period; moreover, I think that the same can be said of his attendance upon the lectures on all the other branches. As a consequence of this unremitting and almost unprecedented application, he learned more in one year than many learn in three, and, as the ultimate result, he passed his examination.

He came under the old (two-year) regulations, as they are termed: he commenced his studies with me in the spring of 1845, and during the ensuing winter he petitioned the College that his summer certificates might be received in lieu of those of a second winter, on the alleged grounds (as well as I can recollect) that he was a family

man with many children, and that his practice in the country was most materially injured as the result of his absence. I also gave him the following certificate, of which I preserved a copy (as I do of most of my business documents), and which I fortunately met with a few days ago, every word of which certificate I can aver is strictly true:—

"I certify that Mr. John Dore Blake has unceasingly and most diligently attended my lectures during the summer of 1845, commencing on the 1st day of May last, and terminating in the latter end of the July following. That he also very diligently dissected during the above period, and performed under my superintendence many of the capital surgical operations.

"That he is also attending with the strictest diligence the present winter course now delivered at the Charlotte-street School of Medicine.

"G. D. DERMOTT.

"Dec. 11, 1845. Bedford-square."

With regard to the manner in which he passed the four years preceding his studies with me I was perfectly ignorant; and as to how far he imposed upon the College by false statements and certificates regarding this matter, also in what degree the College scrutinized his vouchers regarding the said four years of preparatory medical education, is of course a point which concerns the College authorities and Mr. Blake. Certain it is that no honourable man, be he teacher or no teacher, can countenance imposition practised either upon a public body or private individual. Whatever may be the merits or demerits of the parties, imposition and deceit are bad in principle.

I know nothing about Mr. Blake's private concerns, nor have I communicated with him in any way whatever since he passed; but with regard to the story of Mr. Blake having been a pastry-cook, surely this in the abstract is no disgrace; let the low origin of the great Hunter himself be remembered, at least so far as the grovelling estimation of money and family-privileged vulgarities go. It is surely an ominous index of a wretched state of the profession when worldly status and wealth are regarded in preference to professional and scientific requirements.

As stated by you, Sir, in your leader of last week, "If there is anything more calculated than another to overstock the profession it is this—fixing a high price for medical education in the schools, and requiring but a small amount of knowledge to pass an examination."

Alas, Sir, the enormous golden tolls, combined with the system of family patronage, most unchristian in principle, and murderous by wholesale in their tendency—these are the bane of the profession, a curse to the community, and the great source of misery and disappointment to the unsuccessful but deserving medical aspirant.

Your obedient servant,

G. D. DERMOTT.

28, Bedford-square, June 9.

CORONERS AND MEDICAL WITNESSES

[To the Editor of the Medical Times.]

SIR,—In reply to the question by "W. Smith, Esq., Surgeon," in No. 399 of your Journal, "In whom rests the power of summoning the medical witness—is it at the option of the coroner or the constable?" I state, for the satisfaction of the profession generally, that, being placed in a similar position to the one detailed in his communication, I put the same question to a medical coroner of eminence and one learned in the law. His reply was, that, "in the first place, the coroner has a right to select any medical man he pleases, and that he need not call in the one who was in the habit of attending, or who last attended the deceased;" but he goes on to say, "the jury or any one of them has an equal right and power to call in any other medical man or half a dozen if they please, unless they are satisfied with the coroner's nominee." It is therefore obvious that the best mode of proceeding would be to acquaint oneself with the names of the

jury (which can be obtained of the constable), and request any one or more of them to call in the medical attendant of the deceased, who in general would be the most likely to afford a correct clue to the cause of death. In many instances this is only an act of justice due to the medical attendant: various reports go abroad respecting the death of an individual; an inquest is held, *post-mortem* taken place, the opinions of the distressed relatives are received upon professional points of extreme nicety, and a verdict is given to the prejudice of the medical man without any opportunity having been afforded him for explaining or justifying his conduct. Surely in any medical bill for the improvement of the profession some clause should be inserted to make it compulsory that the gentleman who last attended the deceased (and perhaps the family medical attendant also) should invariably be called in.

I remain, Sir, your obedient servant,
FREDERICK RICHARDSON.

Cheltenham.

[The "learned coroner" is clearly wrong. The coroner is governed by the Medical Witnesses Act, which leaves him no discretion.—Ed.] See Lord Denman's famous judgment.—Ed.]

[To the Editor of the Medical Times.]

SIR,—I beg leave to forward, at the request of one of your correspondents, a description of an instrument for the injection of the vapour of ether *per anum*, as alluded to by me in your journal in February last.

I am, Sir, your obedient servant,
J. W. MOSES.

St. Asaph, June 8.

For the sake of accurate description, the instrument may be divided into three parts.

1st. A glass bottle to hold the ether.

2nd. An elastic gum bottle to receive the vapour.

3rd. A long tube, with several perforations at the extremity, for introduction up the rectum.

The elastic gum bottle is fitted, by means of a short tube connected with it, into the mouth of the glass bottle; and the long rectum tube is inserted firmly into the opposite side of the elastic bottle.

Mode of using the Instrument.

The bottle containing the ether is placed in hot water; the vapour ascends and enters the elastic bottle, which, when pressed upon or grasped with the hand, forces the ethereal vapour through the long tube, which has been introduced *per anum* in the first instance; and thus the quantity required may be regulated at the will of the operator or his assistant: an advantage over the respiratory plan, where the inhalation depends upon the patient.

[To the Editor of the Medical Times.]

SIR,—In opposition to the statement promulgated in last week's *Lancet* concerning the number of petitions against Mr. Wakley's Medical Registration Bill, I beg to inform you that on the 10th ult. I forwarded to Sir W. Clay, six petitions against the bill, containing the signatures of forty-nine members of the Tower Hamlets Medical Association, collected in one day; and, had time allowed, many more might have been added; though it is stated in that journal, after a list of petitions in favour of the bill detailed with the utmost minuteness, that the total number of petitions against it to 21st May was five, and the signatures thirteen.

As I think such a misstatement ought not to pass uncontradicted, I shall feel obliged by your giving publicity to the above fact in your next number.

I am, Sir, your obedient servant,
GEORGE C. DALL, Hon. Sec.,
Tower Hamlets Medical Association.
19, Commercial-road, June 9.

Dr. Oschatz has discovered the art of making a very good paper from wood without the aid of nitric acid, or great mechanical force.

BLAKE NO BLOCKHEAD.

[To the Editor of the Medical Times.]
 SIR,—I have seen your notice of Blake's case at Taunton, and really I think a poor man has been very badly used.

Having been for thirteen years employed in the production of pastry and other indigestible trash, and thereby been the cause of no small amount of dyspepsia and innumerable pains in the bowels, his conscience smites him, and he determines upon the only step he can take to remedy the mischief he has occasioned, by becoming "a doctor," or the next thing to it; and, being cloyed with the sweets of preserving with sugar, longs for the more exalted sweets of preserving by physio.

Well, he comes to London, learns that "acid tart." does not mean "sour pie," and in twelve months is found fit to practise as a surgeon!!!

Now, had the excision and removal of the stomachs so disturbed in function been the proper treatment, who could complain? Imposition and false representation notwithstanding, he had been found "fit and qualified so to do, by examination, as attested by the signatures of the Court of Examiners" (but I may be pardoned for entertaining very strong doubts, as to whether his qualifications fitted him for anything else), and, having been found so qualified, I think the man must have much less sense than he had impudence, if, on the polite request of the secretary, he gave up what he had undoubtedly proved his competence to gain, ay, and had paid for, forsooth!

I have been engaged in the practice of medicine and surgery for thirty two years only, but, till now, I always thought that the latter branch required something more than a knowledge of carving a veal-and-ham pasty, or slicing a tongue.

I am, Sir, your obedient servant,

J. LONG SPLEEN, M.R.C.S.E.

London, May 31.

DR. SHEARMAN'S INTERPRETATION OF "THE MEDICAL REGISTRATION BILL."

[To the Editor of the Medical Times.]

SIR,—Dr. Shearman, of Rotherham, has taken upon himself the office of interpreter of the Registration Bill, for the benefit of your readers, and he professes to foresee not only how it will "come out from the committee," but also how it will "work" in practice.

Dr. Shearman may be more competent than the whole body of the Council of the Institute; but his letter in the Journal of May 19, instead of proving his superiority, appears to me merely to reproach and abuse them by his misrepresentations.

Dr. Shearman says in his first four reasons, that "the intended legalization of medical men (not qualified for general practice according to the present law) by the Council and by Mr. Wakley's bill, are the same thing in effect;" whereas, Dr. Shearman knows as well as they do (because they have so often told him), that the Council would legalize such medical men in the first instance only, to prevent retrospective legislation. The doctor's fifth "reason" is equally incorrect.

Dr. Shearman, moreover, informs your readers "what the profession have a wish to demand," but does not tell us how he acquired a greater stock of information on that point than that which the Council have collected. Dr. Shearman knows which class of disputants "think rightly" on the subject, and leaves us to presume, physicians; inasmuch as he is "a physician," and "he thinks rightly."

"There is nothing like leather."

Taking the whole tenour of Dr. Shearman's letter, I suppose he means to say,—"that in the nineteenth century, general practitioners, instead of advancing, should have a retrograde movement in acquiring their general and medical education, and in the extent of their efficiency for performing the duties which they

undertake;" I may therefore be allowed to ask Dr. Shearman, whether he writes for the benefit of the physicians, or for that of the public.

Remaining, Sir, yours very truly,
 East Retford, May, 1847. W. ALLISON.

[To the Editor of the Medical Times.]

SIR,—We, medical practitioners of Thirsk, have severally written to Mr. Churchill, the publisher of "The Provincial Medical Directory," to complain of an inaccurate entry in his work, in regard to the medical qualifications of Wm. Hall Ryott, practising at Thirsk. We take this opportunity of appealing through the medium of your journal to the medical public, whether any value can be attached to the accuracy of Mr. Churchill's publication, when he has so uncourtously refused to furnish us with the information by whose authority such entry was made, or even to acknowledge the receipt of our letters. We must confess that we cannot but regard his conduct with great suspicion, and especially when our correction of the error was in accordance with his own printed request.

The individual referred to is inserted in the directory as having graduated at Edinburgh in 1840, &c. &c.

We have caused the records of the University of Edinburgh to be searched from 1795 to 1846, and no such name as that of William Hall Ryott can be found there.

We are, Sir, your most obedient servants,
 JONAH HORNBER, M.D. Edin., and M.R.C.S. Edin.

THOMAS HAYMES, M.R.C.S.L., L.A.C.I.,
 JOHN HUTTON, M.D. Edin., and M.R.C.S. Edin.

Thirsk, Yorkshire, June 1.

GENERAL MEDICAL ANNUITY FUND.

A meeting of the subscribers and friends of the General Medical Annuity Fund, convened by circular and advertisement, was held on Tuesday, the 1st of June, at the George Hotel, Northampton. Edward Daniell, Esq., of Newport-Pagnell, in the chair.

The Chairman stated that it was unnecessary for him to enter at length into the object of that meeting, nor would he detain them now by any observation either upon the value and importance of the institution sought to be established, as he had already propounded his views so fully to the medical world; and if he could judge from the vast pile of letters upon the table, from the repeated assurances he had received from gentlemen residing in all parts of the kingdom, the necessity of a provision for our decayed brethren, and for widows and orphans, ceased to be problematical. Indeed such an institution was loudly called for, and he had no hesitation in saying that it would be a disgrace to the profession if they allowed either apathy or neglect to prevent the establishment of a general fund for such holy purposes. He had been told by a music-master, that day, that an institution did exist for professionals of that order; and all knew that the mechanics who were connected with the order of persons called "Odd Fellows" had made provisions for their widows and orphans. He heartily hoped a grand effort would be made, but he would detain them no longer, otherwise he should anticipate the secretary's report; he should therefore at once call upon the secretary to read the report.

THE REPORT.

The object of the General Medical Annuity Fund is to secure for the superannuated members of the medical profession, and for their widows and for their orphans, such assistance as may be required, which shall in some measure relieve their necessities. The most limited of resources cannot fail to have seen many instances of necessity and distress in the families of the profession—instances which have arisen from the precarious nature of the profession, from limited sources as to returns and capital, from the expense of purchasing an

insurance, and from the uncertainty of their lives. It is a fact well ascertained that fewer medical men out of a thousand arrive at the age of sixty-six than from the members of any other profession. It was various observations of this kind which induced Mr. Daniell to be anxious to establish a society which should raise a fund, by a limited annual subscription, from the many, which should meet the cases of necessity and distress experienced by the few. It will be my duty to detail to you the steps which have been taken to accomplish this most desirable object, to state to you some of the reasons upon which the calculations of this society have been based, and to suggest for the consideration of gentlemen present such hints as may, I trust, assist you in your deliberations of this day, and enable you to lay the foundations of a society in such a manner, and on so wide a basis, as to secure for itself the confidence and the sympathy of the medical profession throughout the Kingdom of Great Britain. It was about the month of May, 1846, when Mr. Daniell first proposed the establishment of this society, in a letter which he addressed to Dr. Streetten, as the secretary of the Provincial Medical and Surgical Association; and the result of that correspondence was, that at the annual meeting of that association, which was held at Sheffield in the month of July of that same year, Mr. Daniell submitted his proposition for the establishment of an annuity fund, and it was proposed by him, and seconded by Dr. Robertson, "That a committee of the association be appointed immediately to consider, discuss, and arrange the best preliminary steps for the establishment of a self-supporting institution connected with the Provincial Medical and Surgical Association, to be called 'An Annuity Fund for Decayed Members of the Association, and for the Widows and Orphans of Members.'"

On the next day the following gentlemen were announced as forming the committee on Mr. Daniell's proposition for an annuity fund:—Dr. Robertson and Kerr, and Messrs. Terry and Faulcloth, of Northampton; Dr. Mackness, of Hastings; and Messrs. Ceely, of Aylesbury; Rumsey, of Gloucester; Jackson, of Sheffield; Garlick, of Leeds; Haxworthy, of Sheffield; Greenwood, of Horton; Paget, of Leicester; Crosse, of Norwich; and Appleton, of Hitchin.

In the meantime, the attention of many gentlemen having been arrested by Mr. Daniell's proposition, a variety of suggestions were made to him by parties interested in such an undertaking, and the substance of this correspondence was laid before the meeting of the committee, which met at Dr. Robertson's, of Northampton, on Monday, the 8th day of September, 1846, when the rules and regulations were determined upon; but, as those minutes have been very freely circulated, it may not be necessary on this occasion to read that paper. An adjourned meeting of the committee was again held at Dr. Robertson's on Thursday, the 16th day of January, 1846. At this meeting no formal business was transacted, but a long discussion took place upon the principle upon which the society was based, and as to the mode in which its operations could be best conducted.

For some months the attention of your secretary was busily occupied in attending to the business of the society, and in conducting its extensive correspondence and; in company with Mr. Daniell, he attended the annual meeting at the Provincial Medical and Surgical Association, held at Norwich, on the 19th and 20th days of August last, when Mr. Daniell presented a report at one of the meetings of the association. Having read the report, Mr. Daniell addressed the meeting upon the subject, and moved the proposition, "That the conduct of the committee appointed at Sheffield for carrying out the project of a General Medical Annuity Fund be approved by this annual meeting of the Provincial Medical and Surgical Association, and that this fund be considered as an integral part of this association;" and the motion having been seconded by Dr. Hunter, of Lynn Regis, a dis-

discussion arose thereupon. The meeting having been addressed by Drs. W. Conolly, Chambers, and Forbes, and by Messrs. Kitchen and Daniell, the President, Dr. Soulbey, moved, as an amendment, "That this Annuity Fund be not considered an object of this association," which was declared carried, and the original motion was consequently lost.

The decision of the meeting at Norwich deprived the Annuity Fund of that home which its projector had sought for it, and it became Mr. Daniell either to abandon his proposal or seek the establishment of the Annuity Fund as an independent and distinct society. After long consideration he addressed a letter to each of those gentlemen who had subscribed to his fund, as well as to all others who had intimated to him their wish for the establishment of the society. The answers with which Mr. Daniell has been favoured from a large number of his correspondents have encouraged, if we may not even say justified, him in calling this present meeting of the friends and the supporters of the General Medical Annuity Fund; and if I have not already, Sir, wearied the attention of yourself and the meeting, permit me to travel somewhat out of the beaten track of an ordinary report, and deferentially to offer for the consideration of this meeting the suggestions which have occurred to my own mind as relating to the business of the day; and, although I cannot hope that in all points my views will be found to correspond with your own, yet I shall be content, and my end will be answered, if any hint of mine should facilitate your labours, or happily form a channel in which your deliberations may flow.

The question of to-day, then, turns upon this hinge—shall Mr. Daniell's project be abandoned, or shall this meeting take such steps as shall lead to its triumph—its final establishment? I can hardly imagine that you can be disposed to abandon this society, formed as it has been under such auspices, and calculated as it is to meet long-acknowledged wants; that all the letters written, all the statements published, all the services rendered, all the expressions of interest and sympathy which the society has called forth, should all, all become utterly void and useless, and that we can return to our homes and there for ever banish from our minds the recollection that the institution has had an existence—surely not.

Here, then, comes the question—is the assistance already rendered, and the assistance already promised, sufficient to justify further movements in the establishment of this society? To assist you in deciding this question, let us turn and look to the past, and we learn from the statement which I now, Sir, lay before you, that up to last Saturday evening, seventy-five gentlemen have subscribed to this fund the sum of £190, together with donations, and that forty gentlemen have not only promised to become subscribers, but have offered their services as honorary secretaries for their own immediate localities—a service the value of which cannot be too highly estimated, as the interest which these gentlemen will feel in the welfare and progress of the society will tend to its ultimate success.

Under date of Nov. 15, 1845, Dr. Jephson, of Leamington, has promised Mr. Daniell, that if he succeeds completely in establishing the fund, he will give 100 guineas towards its support. Let me now proceed to suggest to you some hints as to the alterations which are required in the rules and regulations of the society. First, then, as to the officers: these, in some cases, will require a change in their names, and I am sure that you will permit me to suggest that our truly excellent treasurer should be appointed your president, and that your treasurer should be the "Northamptonshire Union Bank." The trustees should be gentlemen who are subscribers to the fund; and you will probably recollect Dr. Robertson and Mr. Paget, of Leicester, with Mr. Terry, of Northampton, and Dr. Symonds, of Bristol, to act as such. An augmentation will be required of the number of elective managers, and, in addition to Mr. Fair-

cloth, of Newmarket; Mr. Appleton, of Hitchen; Mr. Elkington, of Birmingham; Dr. Cowan, of Reading; and Mr. Peter Martin, of Reigate, the names of Mr. Rogers, of Newport-Pagnell; Mr. Parker, of Woburn; Dr. Roberts, of Bangor; Dr. Alloway, of Monastrie; and Mr. Lambert, of Sowersby.

You will, probably, feel it right to continue the rules, that no annuity should be paid to a subscriber unless he has paid his subscription for five successive years, as an adherence to this rule will act as a check against any improper application; and the interest of that capital will not only supply a resource for the payment of the current expenses, but will enable the directors to make up those occasional variations in the funds a society, which are to be naturally expected in an institution of this kind. Some alterations will, probably, appear to you as necessary in the rate, as well as in the mode, of the payment of the annuities; and it might greatly conduce to the interests of the society to pay four annuities of £25 each to either superannuated members, or to their widows, or to their orphans, as the case may be, for every one hundred subscribers. If there should not be more applicants than there are annuities to grant, then, as a matter of course, the officers of the institution will decide upon the applicants; while on the other hand, should it prove otherwise, then the secretary would transmit a list of applicants to each subscriber, and the largest number of votes would secure the annuity.

It will also be advisable to determine whether it would not be desirable that the annual meetings of the society should be held in different towns in the kingdom, where gentlemen may reside who feel an interest in the prosperity of the institution. These suggestions, together with other alterations which will probably be resolved on at this meeting, will be required to be worked in mosaic into the present rules and regulations; but as it will be impossible to-day to give that calm attention to the drawing up of the amended rules as such a service requires, you will most probably see fit to determine the general plan of operation, leaving the details to be carried out under the direction of a small sub-committee; and in the meantime it may be thought advisable to transmit this statement of your affairs to each subscriber to the fund. I have the satisfaction of announcing that I have had an interview with Mr. Neison, the author of "Vital Statistics," respecting the society; and, as soon as our rules are matured, he has engaged to examine into their nature and bearings, and he will then be able to determine whether a nominal entrance fee, which should be regulated by the age of the subscriber, could be added to our rules, so that the society should have the benefit of being enrolled under the act of Parliament made for that purpose. It is impossible for me, Sir, within the limits of this report to detail to the meeting the various suggestions which have been made to Mr. Daniell and myself, as to do so would be only to peruse the pile of letters now lying upon the table; suffice it to say, that many of the hints have proved of essential service to us in our labours; while, on the other hand, the tendency, though perhaps not the actual design, of the writers of others would be to convert our simple but comprehensive scheme into an ordinary insurance company. But it cannot be too often repeated, that the design of our institution is to help that class who have not had the power or the disposition to avail themselves of the advantages of life-insurance companies. I think that I may be permitted to say that, in conducting the correspondence of this young but, I trust, rising society, I have spared no labour to detail its objects and its advantages; neither has this been an easy task, for in a measure our society is sui generis, but not completely so, as there are other societies in this kingdom established on somewhat similar principles, but merely local in their operations. Indeed, we may take, as an illustration of our plan, in its development and character, the process adopted in the management of the Art-Union of London.

It may hardly be supposed that, of the thousands which contribute their annual guineas to that society, many do so with a desire to assist the cultivating of the fine arts, and some with the remote prospect of gaining a prize; just as it may prove with us: some may contribute annual guineas upon the principles of the philanthropy, some from a pure sense of duty, and some from a remote contingency of receiving its assistance; while none would refuse or become degraded by obtaining the prize of an annuity, if the chances of this mortal life rendered such assistance requisite. I trust that I may be permitted to close this tedious report by the expression of my wish, that as that society from its small beginnings has become a national society, so may our infant cause come to the stature of a man, and by its manly strength aid every needy member of the medical profession, cheering the widowed heart, and securing to the orphan that comfort and assistance which the visitation of Almighty God may have laid upon him.

H. J. Smith, Esq., of Southam, observed that he would not on any account propose anything likely in any way to obstruct the establishment of Mr. Daniell's fund, which he thought admirable, but it had occurred to him, that we should even go beyond it, and provide homes for widows and orphans. The expenses of renting a house was often of serious consequence to a poor widow; he should like to see homes for widows and orphans in every county town in England, and conceived that the nobility, clergy, and gentry would be ready to assist in such a work.

The Chairman observed that such a thought had struck him, and he believed in one of his letters, he rather thought to Mr. Estlin, of Bristol, he had thrown out the idea; but the funds subscribed to this institution were for an expressed and understood purpose, and could not be directed from that purpose. He was delighted, however, with Mr. Smith's suggestion, and trusted a time would come when such a project might be established.

Dr. Gardner, of London, congratulated Mr. Daniell as to the present prospects of the General Medical Annuity Fund. He felt assured that it must succeed. He admired its simplicity: the calculations could not be otherwise than correct, as four annuities in every one hundred subscribers would clearly yield £25 each; and the capital accumulated in the five years which elapse before annuities would be granted would form a fund to fall back upon when necessary. He highly approved of the provision. He would be delighted to offer his services as honorary local secretary, and pledged himself to exert all the energy he possessed in the execution of his office.

W. Lambert, Esq., of Sowerby, Yorkshire, could not but say that he felt disappointed: for, when he first read Mr. Daniell's proposition, he thought the whole medical world would rise simultaneously to support such a project. It appears, however, he was mistaken; still there was enough to encourage perseverance, and he trusted Mr. Daniell would relax nothing, either in spirit or energy, to complete the noble work he had begun; he should therefore propose "That Mr. Daniell's plan for a General Medical Annuity Fund be proceeded with, and that the report and suggestions of the secretary be adopted." He felt the utmost confidence both in the projector and secretary of the fund.

Dr. Gardner seconded the resolution.

Carried unanimously.

H. L. Smith, Esq., observed that there could be no hesitation in carrying out the project, for it was a capital beginning. He then gave instances of very flourishing institutions, the commencement of which were much inferior to this, nay, some, where the projector, had been both chairman and committee.

Thomas Parker, Esq., of Woburn, asked when annuities would be granted?

The Secretary replied, clearly, even with our present members, four of six would be granted at the end of the five years.

A discussion ensued upon Dr. Shirley Palmer's project, as detailed in the *Medical Times*, when the secretary demonstrated to Dr. Palmer the utter impracticability of his plan on net calculations, drawn from the statistical

meeting was then addressed by Drs. Robson and Pritchard, of Northampton; R. Martin, Esq., of Holbrook, Suffolk; Thomas Parker, Esq., of Woburn, &c.; and the conclusion was, that the General Medical Annuity Fund, proposed by Mr. Daniell, be considered established; that the honorary local secretaries be instructed in their duties, and supplied with proper documents, and that a sub-committee be appointed, to meet at Newport-Pagnell, for the reorganization of the "rules" and final adjustment of all matters for the working of the same; that the sub-committee be composed of the following gentlemen:—Dr. Pritchard, of Northampton; Edward Daniell, Esq., Newport-Pagnell; John Rogers, Esq., Newport-Pagnell; H. L. Smith, Esq., Southam; Dr. Barker, Bedford; Thomas Parker, Esq., Woburn, Beds; and J. G. Leek, Esq., Thrapstone.

Mr. Daniell having read Dr. Jephson's letter, under date of Nov. 15, 1845, announcing his intention of presenting a donation of one hundred guineas so soon as the society was formally established, it was resolved—"That the grateful thanks of this meeting be given to Dr. Jephson for the promise of his very handsome donation of one hundred guineas on the establishment of the society, and the secretary do inform the Doctor of the formal establishment of the General Medical Annuity Fund." It was further resolved, "That the next general and annual meeting be held at Leamington, at such time as may suit Dr. Jephson's convenience, and that he be requested to preside at the same."

N.B.—A financial report, list of members and honorary local secretaries, with new rules and regulations, will be published after the 30th of June next—the conclusion of the second year. Gentlemen desirous of acting as honorary local secretaries will please to signify their intention to Mr. Joseph Staines, secretary, Newport-Pagnell, Bucks.

The following petition has been presented by Mr. Hawes, on the part of the Council of the National Institute, to the House of Commons. It deserves, and no doubt will receive, an attentive reading. The objections to the bill, as well as the general state of the profession, are put in a nucleus, and are concisely given. We call upon the profession to send petitions of a similar nature to the House of Commons forthwith. They cannot work with too much energy in so important a matter:—

"TO THE HONOURABLE THE COMMONS OF THE UNITED KINGDOM OF GREAT BRITAIN AND IRELAND, IN PARLIAMENT ASSEMBLED:

"The humble Petition of the President, Vice-Presidents, and Members of the Council of the National Institute of Medicine, Surgery, and Midwifery,

"Sheweth—That your petitioners represent the wishes and interests of a very large number of general practitioners in medicine, surgery, and midwifery in this country, and have been duly authorized and empowered by their constituents to make known their views in reference to all questions in which the interests of this class of the profession may be involved.

"That your petitioners respectfully urge upon your honourable House that the general practitioners in medicine comprise nine-tenths of the profession in this kingdom,—that they are practising under a great variety of qualifications—some being licentiates of the Society of Apothecaries, some members of the Royal College of Surgeons, and others being possessed of both these qualifications, whilst there are many who hold either a diploma or a degree from a Scotch or Irish college.

"That in consequence of this great diversity of qualification, the general practitioners are

not, as a class, represented in any collegiate institution, and their interests are consequently neglected by the governing councils of those institutions to which they are nominally attached. That this great evil has operated most injuriously upon the welfare of this body—has created jealousies among the different sections of the profession, and has defeated every attempt to carry out a useful measure of Medical Reform.

"That, moreover, the standard of qualification for practice is exceedingly various, and in some instances has been studiously kept low; so that no sufficient guarantee has been afforded to the public of the efficiency and skill of the medical practitioner. That it is expedient that the great mass of the population in large towns and in rural districts, who are almost wholly attended in cases of accident or disease by the general practitioner, should be provided with a medical attendant competent to undertake every exigency, and well instructed in all branches of his profession; it is, therefore, highly necessary that the present arrangements of the profession, which tend so directly to frustrate this object, should be amended, and the profession reconstructed upon a more just, uniform, and comprehensive basis.

"That your petitioners seeing the advantage that has accrued to the profession and the public by the exertions of the Society of Apothecaries in increasing their curriculum of study, and elevating their standard of examination for the general practitioner, earnestly pray that the powers conferred by this act upon the society may not be impaired or subverted by any other measure until the powers of the society, in reference to the education of this class, be transferred fully and completely to another body.

"That your petitioners are strongly of opinion, that this object can be certainly attained only by a separate incorporation of the general practitioners of this country by royal charter, and they feel convinced that, until this incorporation be granted, no measure for the reform of the profession can receive due and unbiassed consideration from the profession at large, on account of the various interests and opinions of its component members.

"Your petitioners believing, therefore, that the future welfare of the profession must depend upon the education and independent action of the class of general practitioners, regard the Bill for the 'Registration of Qualified Practitioners, and for amending the Law relating to the Practice of Medicine in Great Britain and Ireland,' with great dissatisfaction, and believe that it is, in most of its provisions, highly objectionable, and would be prejudicial to the public interests and injurious to the medical profession if it should become the law of the land.

"That the said bill, whilst professing to establish a correct registry of qualified medical practitioners, aims at the subversion of the only protection which the public and the profession possess in the act of 1815, by which the education and attainments of the general practitioners have been raised to their present standard.

"That it would in future permit persons possessing a single qualification as a physician, or as a surgeon, or as an apothecary, only, to practise the three branches of the profession, who, according to the present laws, are unqualified so to do—thereby necessarily encouraging an inferior curriculum of medical education.

"That, without providing an efficient medical board to share the responsibility, it would give the Secretary of State the most arbitrary power over the profession; that it would give an equally arbitrary power to the councils of the several colleges, which might be exercised to the total ruin of individuals or classes, without the offences being clearly defined, and any constitutional appeal provided.

"That the mere certificate of the Registrar would constitute the only legal title to practice—thereby destroying the privileges of the Colleges of Physicians and Surgeons, and also of the Apothecaries' Society.

"That it would tend to continue and give in-

creased facilities for practising medicine to the chemists and druggists, which the interests of the public require should be suppressed or controlled.

"That thus, although usually regarded as a mere Registration Bill, if enacted into a law, it would subvert all the existing relations of the profession, without settling any of the main important points of the long-agitated question of Medical reform—on the contrary, it would leave the question of medical education in the same unsatisfactory state as provisions to the passing of the Act of 1815.

"That your petitioners entertaining these strong objections to the said bill, most earnestly pray that your Honourable House will not allow it to pass into a law.

"And your petitioners will ever pray.

TO THE HONOURABLE THE COMMONS OF GREAT BRITAIN AND IRELAND IN PARLIAMENT ASSEMBLED:

The humble Petition of the Medical Practitioners residing in the Town of Ulverston, and in the Hundred of Lonsdale North of the Sands, in the county of Lancaster,

Sheweth—
That your petitioners have deeply to regret the introduction into your Honourable House of a bill entitled "A Bill for the Registration of Qualified Medical Practitioners, and for amending the Law relating to the Practice of Medicine in Great Britain and Ireland," which does not embrace the fundamental principles of Medical Reform, but is calculated to perpetuate the present dissensions which unfortunately distract the medical profession.

Although your petitioners are fully sensible of the advantages that would accrue to the profession and the public by a legal registration, and by an amelioration of the present laws relating to medical practice, yet they are impressed with a full conviction that the bill, if passed in its present state, will inflict a most serious injustice upon that class of practitioners to which your petitioners belong, and which comprises a great majority of the medical profession.

Your petitioners, therefore, humbly entreat that the present laws regulating the medical profession may not be interfered with until a charter of incorporation has been granted to the general practitioners, based upon the principles advocated by the National Institute of Medicine, Surgery, and Midwifery.

And your petitioners will ever pray, &c.
Signatures to the Petition from Ulverston, and the Hundred of Lonsdale North of the Sands.

Surgeon to the Spalding Dispensary, &c.

CASE I.—TUMOUR OF THE SUPERIOR MAXILLA, INVOLVING A GREATER PORTION OF THE ALVEOLAR PROCESSES OF THE RIGHT SIDE, TOGETHER WITH THE OPERATION FOR ITS CURE.

Robert M., aged fifteen years, a scrofulous youth, was admitted into the Union Infirmary, May 7, 1847. His mother informs me, that about three months since he first began to suffer from uneasiness in his right cheek, accompanied with slight swelling; he suffered more from the pain during the night than day. After a time the second molar tooth became loose; he then applied to a medical gentleman, and requested him to extract it; he did so; the tooth was quite sound, and a small fleshy tumour was pushing it out of the socket. After the tooth was removed the tumour grew rapidly, in spite of caustic and the application of nitric acid. The friends of the youth, being alarmed for his safety, brought him to me for my advice; upon looking into his mouth I observed a fleshy, lobulated, spongy sort of tumour, occupying half of the mouth, overlapping a greater portion of the tongue, and projecting to the fauces, and filling up the space between the cheek and the teeth, and bulging the former considerably outwards; it was firmly attached to the socket from which the second molar had been extracted, and involved the gum and alveolar processes beyond it: a portion of the tumour was in a state of ulceration from the application of escharotics; it bled freely if touched. I called a consultation of medical gentlemen, when it was unanimously decided that the tumour had its origin from the alveolar ridge and socket from which the tooth had been extracted, and that it was of that character that nothing less than the complete removal of the diseased mass, together with that portion of the superior maxilla from which it originated, would suffice for its cure. I therefore, on Thursday, May 11, in the presence of my medical friends, removed the tumour, including a portion of the superior maxilla, extending from the canine tooth to its tuberosity, in the following manner:—The boy being seated in a chair and his head supported by an assistant, I commenced by making an external incision, extending from below the malar bone, a little in front of its junction with the zygoma, to the upper lip, which I completely divided; the superior coronary and transverse facial arteries were secured, and the flaps reflected back, when the tumour was fully exposed. I then extracted the canine tooth, and afterwards, with a scalpel, made an incision along the palate, also through the soft parts externally, where I intended to divide the bone; with a strong pair of bone forceps I now cut through the superior maxilla, where I had previously extracted the tooth, and afterwards at its tuberosity, and then placed a broad chisel above the tumour, and with a hammer drove it into the substance of the jaw, and wrenched the piece removed from its bed. There was a good deal of hemorrhage, but no further vessels required ligature. Having cleared out the mouth of clots, and the bleeding having ceased, I sutured the wound in the cheek together by two

sutures, and placed one needle in the upper lip, with a twisted suture, as for harelip, and applied a few strips of plaster. When I saw the boy in the evening I found him comfortable, and very little bleeding had taken place: I ordered him to have sago and rice-milk, and gave him an opiate for the night.

May 16, ten A.M. He has passed a very good night; the wound in the cheek appears to be uniting; a slight bloody discharge has taken place from the mouth. Seven P.M. Going on favourably; repeated the opiate.

May 16. Has passed another good night; to have an enema immediately; has taken plentifully of sago and rice-milk. Seven P.M. Has had a copious evacuation, and feels much better; to discontinue the opiate.

May 17. Slept well all night, and wishes to get up. The wound in the cheek has united; to have beef-tea, sago, &c.; bowels have been well relieved again.

May 19. Progressing favourably; removed the plasters; the wound looks healthy; also removed the interrupted sutures; the twisted suture at the margin of the lip I thought it prudent to allow to remain. To walk daily in the garden.

May 29. Up to this date the boy has done remarkably well, and his friends being desirous of taking him home, I allowed him to leave the infirmary with an understanding that he should be brought to me once or twice during the week.

CASE II.—CASE OF CONGENITAL PHIMOSIS, WITH THE FORMATION OF 118 CALCULI UNDER THE FORESKIN.

Robert Franks, aged eighteen years, a fine athletic youth, was admitted into the Union Infirmary April 9, 1847. He stated that he was much troubled with gravel, and that he had been attended by an apothecary, but "his medicines did him no good." He saw him only two days before his admission, and gave him a bottle of medicine; he states that he has come into the union infirmary to be cured of his complaint. Upon examining the penis as he stood up, it presented a most singular appearance: the head of it was the size of a large orange, and hung down between his thighs; indeed, the weight was such as to elongate the penis considerably; the veins of the prepuce were much enlarged. Upon grasping the enlarged prepuce, and rotating it about in the hand, a distinct grating could be felt, indeed, it was exactly like handling a bag of marbles; the orifice of the prepuce was so small that I had great difficulty in passing the end of a probe through it. He states that when he passes water the prepuce first fills, and swells out; he then grasps it with his hand, and forces the urine out through the contracted orifice; he did this in my presence. He has never been able to have sexual intercourse; indeed, when an erection takes place, it must present a very formidable appearance. Having stated to him the nature of his complaint, and the operation necessary for its cure, he begged I would at once relieve him, as he wished "to be like other men." I, therefore, without further ceremony, slit up the prepuce by means of a direct and bistoury, and turned out from beneath the foreskin 118 calculi, varying from the size of a millet-seed to that of a nut; the glands penis was remarkably small and shrunken. Having washed the parts well out, I ordered warm-water dressing. The youth went on afterwards very well, and on the 26th of April was discharged cured. The calculi were white and polished, with an uneven surface, and, when divided, presented a laminated appearance, and gave out a strong ammoniacal odour: they appeared to me to be composed of the ammoniacal phosphate of magnesia.

VENTILATING PANES.—Amongst the last inventions to facilitate good ventilation, Mr. Bowie has recently registered a pane of glass wherein small holes are drilled obliquely, an inch or an inch and a half apart, thus giving an upward direction to the current, with a view of avoiding inconvenience to the occupiers of the apartment.

THE LATE POISONINGS AT KENSAL NEW TOWN.

On Wednesday morning Mr. Wakley, M.P., and the jury assembled on Tuesday, the 1st inst., at the Porto Bello Arms, Kensal New Town, resumed the inquiry into the circumstances attending the deaths of Thomas Hickman, aged thirty-three years; James Bonomay Hickman, aged nine years; Harriet Elizabeth, aged six years; Mary Anne, aged four years, and ten months; John, aged three years; and Henry, aged one year and five months; the unfortunate father and five children who died from the effects of poison on Sunday, the 30th ult.

Anne Sullivan was the first witness called. She deposed that she lived close to the cottage of the deceased. About two o'clock on the afternoon of Sunday, the 30th of May last, the deceased, Thomas Hickman, sen., came and called to her. She went to him, when he told her he wanted her to see his wife and children. She immediately went to the cottage, when he asked her to look at his wife and children, as they seemed to be very sick after only eating some rhubarb pudding. She found them all vomiting and evidently very ill, and asked him if she should fetch a surgeon, when he told her to go to Mr. Abercromby, the surgeon, which she did, and he immediately attended.

Mr. John B. Abercromby deposed that he was a licentiate of the Apothecaries' Company, residing at Kensal New Town. On the afternoon of Sunday, the 30th of May, between two and three o'clock, he was called in by the witness Sullivan, and on entering the cottage he found the father, mother, and aunt all vomiting. He asked them what they had eaten, and the deceased Thomas Hickman answered, some rhubarb pudding, which had disagreed with them. Witness said he was certain it was something more than the pudding that had disagreed with them, and asked if they had not also eaten of some meat, seeing some baked mutton on the table; but he was informed that they had only partaken of the pudding, and that sickness had immediately followed. Witness, therefore, considered that they had been poisoned, and sent home for a medical gentleman, who was dining with him, and who instantly attended. Witness asked them if they had any suspicion of any one having wilfully poisoned them, but Hickman said he had not. Suspecting from the symptoms that they were suffering from the effects of arsenic, witness mixed some flour of sulphur with yolk of egg and milk, and administered it. Mrs. Hickman and the aunt were at that time incessantly vomiting, and, considering that it would prove a serious case of poisoning, witness sent off a messenger for Dr. Barnes, of Notting-hill. After witness had been there about an hour and a half, Mr. Brown, surgeon, of Kensal-green, came in, and was immediately followed by Dr. Barnes. That was about four o'clock. The vomiting had by that time in some measure abated, and witness and the other medical gentlemen considered it would be an advantage to keep it up. The boy James, however, soon fell into a state of collapse, and died about six o'clock. Several others were soon similarly affected, upon which mustard poultices were applied to the chest, and ammonia, &c., were administered to them; but they gradually sank, and four more of them died before twelve o'clock at night. Thomas Hickman, the father, did not die until the next day (Monday), at twenty-five minutes past twelve o'clock at noon. The latter never rallied, but yet he retained his senses until within a few minutes of his death. The remaining three of the nine persons, viz., Mrs. Hickman, Carolina Bonomay (her sister), and Thomas Hickman, (the eldest son), survived.

The Coroner: What marked difference did you remark in the symptoms of those who are now alive and those who sank?—Witness: Their pulse was not so low and they did not fall into a state of collapse. Had omitted to state that he had also administered hydrauto pyroxide of iron as an antidote.

By the Coroner: Did not use the stomach-pump in any of the cases, as it would have been choked up by the food drawn. Had since opened the bodies of Mary Anne and Harriet Elizabeth Hickman. Mary Anne, who was aged four years and ten months, died at half-past six o'clock on the Sunday night, eight and a half hours after swallowing the pudding. Witness then proceeded to describe the result of the post-mortem examination.

Coroner: What do you consider the cause of death?—Witness: I consider the cause of death was poison. I have ascertained the nature of the poison to be arsenic, having found it in the contents of the stomach and in the intestines?—Mr. Abercromby: Not in the cases of either Mary Anne or Harriet Elizabeth.

The Coroner: Now, in the case of Harriet Elizabeth what difference did you discover?—Witness: Her oesophagus was pale throughout, while the other was rosy; also at the beginning of the ilium in the first was an injection, but in the other it was at the end. The cause of death was the same in the one as it was in the other. The contents of both stomachs contained proof of poison. Reich's and Herapath's tests slightly showed arsenic. The appearance resembled those of spasmodic cholera, and the stomachs were all collapsed.

The Coroner: Did you make any inquiry as to who made the pudding?—Witness: I consider the cause of death was poison. I have ascertained the nature of the poison to be arsenic, having found it in the contents of the stomach and in the intestines?—Mr. Abercromby: Not in the cases of either Mary Anne or Harriet Elizabeth.

The Coroner: Now, in the case of Harriet Elizabeth what difference did you discover?—Witness: Her oesophagus was pale throughout, while the other was rosy; also at the beginning of the ilium in the first was an injection, but in the other it was at the end. The cause of death was the same in the one as it was in the other. The contents of both stomachs contained proof of poison. Reich's and Herapath's tests slightly showed arsenic. The appearance resembled those of spasmodic cholera, and the stomachs were all collapsed.

The Coroner: Did you make any inquiry as to who made the pudding?

The witness replied that he had asked who had made the pudding, and Caroline Bonomay (the aunt) replied that she had. He then asked her if any one had access to the flour before it was made, to which she replied in the negative. He also asked her if any one had access to the pudding after it was made, to which she said, "No." At that time Mr. and Mrs. Hickman and her sister were in the front room together, and the children in the back room. The aunt then appeared to recollect, and said it must have been that powder which she had found in a bag, and which she had mixed into the flour-bag out of another flour-bag. Witness immediately asked how much it contained, when she said about a tablespoonful and a half. Mrs. Hickman then said to her husband, "Hickman, it must have been one of those white powders which you keep about the house." Hickman then said, "Oh! then it's nitrate of silver." Witness replied, "No, it's not that, it's something else." Hickman then said, "It then must have been that white arsenic which I have had for many years, and which I thought had all been thrown away." Witness immediately asked to see the paper in which it was, and the aunt said she had used it to light the fire, which she said was the reason that the emptied one bag into the other. Neither bag was to be found. Did not know what had become of the second flour-bag. Had searched the house, but had not found it.

The Coroner: After that statement was made to you did you make any remark?—Witness: No, I did not.

The Coroner: Did Hickman, sen.?—Witness: No, he did not; nothing beyond that the arsenic had been kept in a glass bottle, which had been broken, and it had then been put into paper. Witness knew before that he had arsenic in the house, as he had been in the glass trade. Hickman made no charge against any person of having given it purposely. He made no accusation whatever against his wife's sister, but seemed only to blame his own carelessness in not destroying it before. Had seen Hickman privately, but he never stated anything tending as a charge against any one. Nothing whatever had occurred in witness's presence to indicate even a suspicion in his mind of the arsenic having been intentionally administered. Witness noticed no

difference in the vomiting of the wife or the sister from that of the others of the family. Had heard a great deal respecting the case in reports out of doors, some of which, to his own knowledge, were altogether unfounded.

Mr. George Brown deposed that he was a member of the College of Surgeons, and resided at Kensal-green. He had heard the statement of Mr. Abercromby as to the general treatment and appearances, which he fully corroborated, and would only state, in addition, that, when he first went there, about a quarter past four o'clock on the Sunday afternoon, he found the pulse of the children scarcely perceptible, and that they were in a state of collapse. The pulse of the two grown-up females and the father were much stronger.

Mr. Abercromby was here recalled, and asked by the coroner if, when Hickman spoke about the bottle which had contained the white arsenic having been broken, he stated when it was; to which witness replied, that his impression was, that Hickman said it was when he removed to his present cottage, about three months ago.

Mr. Brown further stated that he had made a post-mortem examination of two of the bodies, and that in his opinion their deaths arose from arsenic, as he had found arsenic in the contents of the stomach. Found it all in a very large quantity. The father suffered so much more than the others that a blister was put on him.

Dr. Robert Barnes, of 1, Park-road, Nottingham, deposed to having been present at all the post-mortem examinations, and also on the Sunday afternoon, and he fully agreed with the statements of both Mr. Abercromby and Mr. Brown as to the general treatment and appearance of the sufferers.

The Coroner said the evidence given by the medical gentlemen just examined had placed beyond doubt the fact that the deceased had died from the effects of arsenic. All they wanted now, therefore, was to learn under what circumstances the poison was administered.

Mrs. Sullivan recalled: When witness went to the cottage the elder Hickman told her to look at his wife and children, who were intolerably sick, and he sent her for Mr. Abercromby. Heard that gentleman ask if anything had been put into the pudding; and heard the aunt say that at half-past six that morning she wanted a piece of paper to light the fire, and took a paper bag off the shelf. Hickman did not accuse her sister-in-law of having done it intentionally. From all that witness saw and heard of the affair she was convinced that it arose from accident. Hickman had been in the glass trade, and tried experiments at home on glass. Witness was in the habit of seeing them all every day. Never heard any threats uttered by either the wife or her sister against any of the members of the family. Hickman said he thought the arsenic had been destroyed long ago, and he also told witness that no one knew in the house that it was arsenic but him. Witness was present when the pudding was made. Mrs. Hickman and her sister began it together, but the former cut her finger, and therefore the sister finished it alone. The pudding was mixed in the dish in which it was baked. Mrs. Hickman put the flour into the dish, and, after she had mixed it, finding there was more in one compartment than in the other, she took a handful out and put it into the other.

Thomas Hickman deposed that he was not quite twelve years of age, and that he was the son and brother of the deceased. They sat down to dinner on the Sunday in question between one and two o'clock. It was his mother who told him the dinner was ready. They began with the pudding first. His mother and aunt made it. Had never seen any powder about, or known that there was any poison in the house. Flour was generally kept in the front room in a cupboard. Did not see the second flour-bag after the pudding was made. Had never heard any person, either in the family or out of it, threaten to poison his father.

His mother was first taken ill, and then his sister Mary was the second, and he was the third. When taken ill he felt very much in pain in his chest, was very much burning in his throat. The mother died in on the Saturday from the effects of the poison, ate a plateful of the pudding.

Mrs. Harriet Hickman was next examined, her sister being first removed from the case. She deposed that she was the widow of the deceased. Her sister came into her room on the Sunday morning, about half-past six o'clock, and witness was not well, and she would light the fire. She looked about for some paper, and found a flour-bag, and asked witness what was in it. Witness told her, believing at the moment that it was, and her sister put it into the other flour-bag and used the powder. The week before witness's husband had opened a basket which was in the back room, and contained things he had used in his business, and amongst other things that he took out a bag with some powder in it, and he asked witness what it was. She told him that she thought it must be arrowroot, that had been left from the time some of it had been used when the children had the measles, and she took and put it on one of the shelves in the back room, from which her sister must have taken it. Her husband used to keep a great many things in his possession, with which he used to make experiments in different kinds and colours of glass in small crucibles over the fire. Her sister had only left her situation on the Tuesday before, and came there to stay till she got another.

Caroline Bonomay was then called in and examined. She gave an exactly similar account of the affair, saying that she took the paper bag off the shelf in the back room, and after speaking to her sister about it said, "There can be no harm in turning this out into the other bag," and did so, and lighted the fire with the bag. There was only about a tablespoonful and a half of powder in it. She ate a plateful herself, and was going to take some more, but at that moment her sister called her to the children, who were vomiting in the other room.

Policeman Anderson, D 35, who was called in, about four o'clock on the Sunday afternoon, deposed that although he spoke to Hickman and his wife on the subject of the poison they gave no one into his custody, nor accused any one of having wilfully poisoned them. They had every opportunity of doing it had they thought so.

The Coroner then addressed the jury, and said there had been a great many most unfounded reports in circulation respecting the case. It was in his opinion a most deplorable thing that a calamity like that, in which a father and his five children had lost their lives, was not sufficient, and that persons should raise reports injurious to the characters of the survivors, in order to make things worse. He had adjourned the inquest in order that every inquiry might be made into the case, and now there was not a single tittle of evidence left which could throw any additional light on the question, the evidence having clearly shown that the deaths were the effects of the arsenic. That point being settled, the jury had also heard the evidence of the survivors, in which there was not the slightest disagreement, and which, he was convinced, was true. It, however, certainly was a melancholy case that a father of a family should keep poison in the house, as had been stated, and make experiments with it over the parlour fire.

The jury immediately returned a verdict, "That the deceased persons had died from the effects of arsenic eaten in a rhubarb pudding, mixed with the flour by the wife and sister in ignorance of its nature, it having been left carelessly within their reach on a shelf by the husband, but not with evil intent,"—this being a verdict equivalent to "Accidental Death."

The inquiry occupied several hours.

THE POTATO DISEASE.

A very full meeting of the Royal Agricultural Improvement Society was held, with closed doors, on Friday week, for the purpose of receiving authenticated reports of the actual condition of the potato crop, with a view of elucidating to what extent, if any, the last year's blight had shown itself. The Duke of Leinster presided. The Duke of Leinster, the Earl of Charlemont, and several other leading members were present.

The meeting was held at the Duke of Leinster's residence, where he had received various communications from several places respecting the state of the potato crop, giving different accounts of its appearance up to the last few days. Messrs. Higgins and Sons, of College-green, stated that they had planted a lot of "early maincrop" in the open ground in January last, the seed of which had been sowed with great care; and about the same time they had also planted a few sets in a greenhouse. They both came up well, and appeared healthy until the early part of last week, when they all manifested unquestionable symptoms of disease, similar in its appearance to that of last season. Those that were under glass and those in the open air were affected at the same time and in the same manner.

Messrs. Purdon, proprietors of the *Farmer's Gazette*, stated that they had issued a circular to the secretaries of the different local farming societies, requesting them to send in returns of the exact state of the crop in their immediate neighbourhood, and the great majority of returns already received described it as still apparently in a healthy state, and all the other crops looking exceedingly well.

Mr. Monsell read extracts from reports of several persons employed by the Board of Works, in drainage, from different parts of the country, stating that the disease had attacked the stems generally underground, though the leaves and stalks appeared still healthy and flourishing.

A letter was also read from Mr. J. M. Spong, a practical agriculturist in Carlow, stating that within the past week he had travelled over large portions of Carlow, Kildare, and the Queen's County, in company with some gentlemen whose names he mentioned, and that they had found the first symptoms of the disease existing generally. It manifested itself in the stem, low down, near the set or seed, under the earth, and afterwards advanced into the leaves and branches. It appeared to have attacked the autumn or early-planted potatoes to the greatest extent; and even the English reds, which had escaped the disease last year better than any others, appeared generally affected at present.

Mr. Spong's statement was accompanied by several specimens of potato plants, which he stated he had procured in different places in the above counties, and which were examined by the council, appeared to contain evident symptoms of the disease as above described. They were also inspected by Professor Allman, and other practical and scientific gentlemen, who fully concurred in the above opinion, and considered that the disease resembled in its leading features the epidemic of last year.

Considerable discussion then ensued as to the course it would be most prudent and advisable for the council to pursue, so as to produce the best information relative to the exact nature and extent of the disease, and to suggest such remedial and precautionary measures as might be deemed prudent and advisable. The chairman was clearly of opinion, in which his Grace the Duke of Leinster and the other members fully concurred, that their best course was to seek, through the machinery at their command, for the most accurate information on the subject, and, at the same time, to take advantage of the present opportunity to suggest such substitutes for the present crops as may, upon inquiry, be deemed advisable, and can be planted in time.

Accordingly it was ordered that a circular should be prepared and sent to the secretaries of the different local farming societies in connection

with the central authorities, that the council, having received reports of the state of the country, leading them to believe that the potato crop in those districts was already showing partial signs of disease, deemed it right to direct the attention of all growers throughout the country to the necessity of immediately examining their respective crops; and, in order to enable them to form a sound opinion on their condition, they subjoined the following short statement of the principal external marks by which the disease can be generally recognised, namely:—

That the disease is to be found in that part of the stem which lies under ground, and may exist although the leaf appears perfectly healthy. That it is shown sometimes on that portion of the stem near the surface of the ground, but more frequently near the seed or set, and presents the appearance of a bruise, or dark mark, upon the surface.

The council further recommend, in any instance where a crop appears decidedly affected with this disease, the immediate substitution of Swedish or Aberdeen turnips, or of mangel or cabbage plants, where they can be obtained, all of which may be dibbled into the drills between the potato-stalks without any additional manure.

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma of this college, were admitted members at the meeting of the court on the 28th ult., namely, Messrs. Daniel Badoock, Sheffield; James Robert Lane, Cranford, Middlesex; Charles Rouse Durell, Jersey; Joseph Thomas Clover, Aylsham, Norfolk; Thomas Poole Collier, London; Thomas Rhys, Penlline, Glamorganshire; Laurence Clarke, Longford, Ireland; William Prichard, Abergavenny, Monmouthshire; Joseph Anthony Simons, London; Robert Davies, Llanywst, Denbigh, North Wales; John Chamberlayne Ingles, Cape Breton, North America; and Benjamin Dinnel, Hull. At the same meeting of the Court of Examiners, Mr. Robert Hastings, a member of the Edinburgh College, passed his examination for full surgeon in the Royal Navy.

APOTHECARIES' HALL.—Gentlemen admitted members May 20:—Charles King, George Milburn, William Dawson Wilkes, John Smith, Samuel James Augustus Salter, Richard Jones, Ellis Southern Guest, Charles Frederick Augustus Courtney, and William Honner Fitzpatrick. May 27:—Charles Sproule, Edward Dawson Alhinson, William Henry Paine, Henry Hides, Alexander Mundell Champness, Edwin Younge, Francis Henry Blaxall, Henry Heath Corbould, Henry Stevens, and Thomas Hobson. June 3:—George Roper, William El-lery, Mark Hazlewood Clayton, Robert Megginson, John Bourne, Charles Wankford Currie, William Denton Dibb, Robert Muriel, Squire Sprigge, George Houseman Macnamara, George Bruce, and Henry Slade.

NAVAL APPOINTMENTS.—Surgeons. Dr. H. W. Mahon, to be surgeon-superintendent of the *Minerva*, convict ship; M. Thompson, to the *Odin*.—Assistant-Surgeons: A. R. R. Preston, to the *Buildog*; J. W. Bradshaw, to the *Victory*. Assist.-surgs.: Dr. A. Armstrong, F. Manger, and Henry Mathias, to *Caledonia*; W. Calhane, and James Wood, to *Plymouth Hospital*. Assistant-Surgeons R. Vinigle, H. French, and T. B. Purchas, to the *President*.

WARRINGTON, June 4.—67th Foot: Thomas Blatherwick, gent., to be Assist.-Surg., vice Webb, appointed to the Staff. 68th: Assist.-Surg. James M'Nab, M.D., from the Staff, to be Assist.-Surg., vice Bowie, deceased.—89th: Assist.-Surg. George M'Clure has been allowed to resign his commission.—Hospital Staff: Assist.-Surg. Vere Webb, from the 67th Foot, to be Assist.-Surg. to the Forces, vice M'Nab, appointed to the 78th Foot.

REWARD OF ILLUSTRIOUS MEDICAL MEN.—The Shah of Persia has conferred on Dr. Ernest Cloquet, the decoration of the order of the Lion and the Sun, as an acknowledgment of the services rendered to his royal person, and to his subjects during the time the cholera prevailed in the country.

MELANCHOLY DEATH.—Mr. Benj. Sheppard, of Worcester, in a fit of temporary insanity, committed suicide by taking prussic acid on Tuesday last. Having exclaimed "it's all right!" he expired in a very few minutes.

OBITUARY.—On the 22nd ult., aged sixty-seven, Dougal Campbell, Esq., M.D., half-pay surgeon, Royal Artillery, at Boulogne-sur-Mer, where he had been practising as physician for upwards of twenty-five years, sincerely regretted by all who knew him. He claimed the earldoms of Annandale and Hartfell, and his brother, the late Colonel William Claud Campbell, had claimed the earldoms of Crawford and Lindsay. On the 2nd inst., at Warrington, of fever, caught while attending to his duties at the Fever Hospital, Mr. William Morley, resident surgeon of the Warrington Dispensary.

MORTALITY TABLE.

For the Week ending Saturday, June 6, 1847.

Causes of Death.	Total.	Average of 5 Winters.
ALL CAUSES.....	786	914
SPECIFIED CAUSES ..	784	909
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	160	166
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat	93	99
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	122	158
Diseases of the Lungs, and of the other Organs of Respiration	202	275

COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the THEATRE OF QUEEN'S COLLEGE, Birmingham.

By SAMUEL WRIGHT, M.D.,

Physician to Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham; Physician to the General Dispensary; Extraordinary Member, and formerly Senior President, of the Royal Medical, Royal Physical, Hunterian Medical, and Cuvierian Natural History Societies of Edinburgh, &c.

Subacute and chronic rheumatism; the former very commonly met with in practice, not a sequela of acute rheumatism, observations on the character, continuance, and cessation of the latter, various causes producing subacute rheumatism, illustrations, general symptoms of it, rheumatism resulting from cold caught during an attack of dyspepsia or disordered general health; hereditary rheumatism, resemblance of this to gout, points in which they differ, lithate of soda in gout, and lithate of soda in rheumatism, rheumatism affecting parts that have been injured or over-exerted, illustrations, parts in which subacute rheumatism chiefly attacks, particulars in which this differs from acute rheumatism, treatment of the former, illustrations and observations upon them; chronic rheumatism, its characteristics, cases, treatment.

GENTLEMEN,—To-day's lecture will embrace the subjects of subacute and chronic rheumatism.

Subacute rheumatism is the most common variety of the rheumatic affection which you meet with in practice. It exhibits a diversity of character according as it may be more or less severe, and few or many joints may be affected by it. It is not a *sequela*, properly so called, of acute rheumatism; this latter leaves no analogous affection as its natural sequence. Acute rheumatism comes and goes, it may be for a series of years, leaving its subject no worse for its visitations except in so far as nervous debility, through over-active treatment, or injury to some vital organ, from metastasis, may be the issue of it. I have met with cases in which acute rheumatism of the severest kind has been endured every two, three, or more years, for nearly a quarter of a century, and yet the sufferers apparently no worse for their many seizures. The attacks for which I have attended them have been of the most urgent kind, and they have told me that their previous ones have been similar, yet, the attack over, and their strength restored, you would not have suspected that they had ever endured affliction worthy of the name.

Acute rheumatism, *per se*, is not a dangerous affection, except in so far as heroic treatment and metastasis may make it so. The former I advise you to guard against; the latter always to be prepared for. Avoid doing too much, whilst the ailment confines itself to superficial parts; do enough, and do not delay it, when secondary inflammation seizes any deep-seated organ. But, as I have said, there is no danger so long as the limbs only are affected; the ailment may be tedious and painful, but it will be little else;

good management will lessen both the duration and the degree of the attack.

In the majority of cases acute rheumatism wears itself out, so to speak. It is not uncommon to find people in adult or advanced life strangers to rheumatism in any form; who were martyrs to its inflammatory type in their younger days. In some instances you have substitutes more formidable than the original, in others, wandering pains in this joint and that, with every change of season, tell us that the articulations have not come off unscathed for the onslaughts they have suffered. These, however, cannot properly be considered *sequela* of the acute affection; local weakness, left by this latter, is, perhaps, the remote cause, or opportunity rather, of the subacute form, over-excitation or injury of a part will similarly predispose, as I shall hereafter illustrate to you. In ninety-nine of every hundred cases of subacute rheumatism that you meet with you will find that the ailment exists *per se*, and has not had acute rheumatism for its precursor. Various causes produce it. Let us glance at a few of them; what I am now going to say will recall to your minds many of the cases that have passed before us during this session.

A patient comes to you complaining of "aching all over him," as he calls it; he is as sore, he says, as if he had been beaten. Some of his larger joints are painful, particularly on motion; they are a little tumefied, and their heat is above the natural standard. These pains are aggravated by warmth, they are, perhaps, relieved for the first few minutes after having got into bed, but directly that heat becomes confined and accumulated, the pains increase, until the patient feels the bedclothes intolerable, and throws them off in agony. With this state, however, there is little or no redness of the affected parts; there is but trifling, if any, fever; the pulse is scarcely above the natural standard as a rule, and when above this, the impetus is not increased; the artery is easily compressible; there is no rotundity, resistance, or jar under the finger; the tongue is loaded with a white or yellowish white fur; the complexion looks unhealthy, and the eyes dull; there is no appetite, but frequent thirst, the urine is scanty, and loaded with lithates; bowels constive. You learn that the patient has been dyspeptic for some time, and one day sat in a draught, got his feet wet, was soaked in a shower, or slept one night in a damp bed; and hence his trouble. What in

another case might have given rise to simple fever, or favoured the accession of any prevalent epidemic, has in this instance originated sub-acute rheumatism. In common parlance, such a case is called "a cold."

An individual, dyspeptic, or otherwise disordered, puts on a damp shirt, and, not liking the trouble of taking it off again, presents himself before you the next morning, complaining of rheumatism in his shoulders and elbows, and perhaps in his loins. Another has sat on a damp bank, and lumbago or sciatica is the consequence of his folly. A woman, during the menstrual period, gets her feet wet, and she has rheumatism in her knees very shortly; perhaps it flies thence to the bowels, or to the peritoneum, and the inflammation, if not soon arrested, very soon ends fatally; perhaps the rheumatism flies to the uterus, which then becomes affected with troublesome periodical pains, and its natural discharge is arrested.

A sudden chill, local or general, occurring to an individual out of health, and especially in his digestive organs, is particularly apt to be followed by rheumatism; and this is, more than any other ailment, liable to repeat itself.

Other cases you meet with in which there is an hereditary rheumatic diathesis. This is common in the subacute, but rare in the acute variety of the affection. In the former, you sometimes find that all the members of a family are subject to it, and they will trace its pedigree up to a remote grandfather. Here we perceive a great resemblance to gout, not only in the transmission of the ailment, but in the gastro-intestinal disorder which usually accompanies it. In the rheumatism, however, there is more lactic acid found in the secretions than in gout; in the former, again, lithic acid is generally abundant in the urine; in the latter, it escapes with the perspiration as lithate of soda, or is deposited in this state in the joints, constituting gouty concretions. Lithate of soda is a comparatively rare formation in rheumatism; it would seem that the lactic acid takes the soda at the expense of the lithic. Certain it is, however, that you find lithate of soda in gout, and lactate of soda in rheumatism.

Again, you meet with cases in which joints and limbs are rendered liable to rheumatism through injury or over-exertion. A man falls down and sprains his knee; it troubles him for a time, but at last gets well. If he inherits the rheumatic diathesis, the first cold he takes flies

to that knee, and it will be strange if every subsequent cold do not similarly affect it. Let his stomach get out of order, and the knee will pain him. I am at this time attending a lady, aged thirty, who, three years and a half ago, fell down stairs and hurt the lower part of her back. Since that time, every attack of cold, or of dyspepsia, however slight, has been followed by a repetition of the original pain. I saw a somewhat similar case the other day: a patient, under the care of my colleague, Professor Berry, fell, and pitched upon the point of his right shoulder. The original injury was remedied some time ago, but the man has since suffered from very severe rheumatism in the part. You will find that mechanics and labouring men are mostly subject to rheumatism in those parts of their bodies that are chiefly exercised. Blacksmiths, shoemakers, and others whose arms are mainly employed, if they suffer from rheumatism, generally have it there. Muntz's man, you remember, who was an out-patient some time ago, had this complaint in his left arm and shoulder. He was accustomed to wield a heavy hammer, and I was surprised that it was not the opposite limb that was affected, but learned, on inquiry, that the man was left-handed. Goddard, whose case I spoke of in my last lecture, was a joiner, in an establishment where he was required to do a great deal of sawing and planing. His rheumatic seizures have always been confined to the right arm and shoulder. Millers, who carry heavy weights on their backs, are liable to lumbago and sciatica; so are gardeners, and others accustomed to much digging. The out-patient Pearce, who was so severely afflicted, is a case in illustration. Postmen, and other great walkers, are particularly subject to rheumatism of the legs; old hounds are often crippled with this painful affection.

Subacute rheumatism chiefly seizes upon muscular parts, such as the shoulder, loins, and hips; or parts well supplied with ligaments, as the knee, ankle, and wrist. It is more liable than acute rheumatism to affect muscles solely; and is less liable than this to metastasis to internal organs. In its transference from superficial to deep-seated parts, it rarely shows an increase of activity, at least of an inflammatory nature.

Subacute rheumatism, is not a *sequela* of the acute form, as I have said; it differs from this in the absence, or the great mildness, of the sympathetic fever, and in the local affection not furnishing distinctive evidences of inflammation. The parts are swollen, stiff, and painful, but they are not redder than natural; there is rarely an increase, and often a diminution, of heat. This, in an artificial form, generally increases the pain, and hence the ailment has sometimes been denominated "cold rheumatism," to distinguish it from the other, which was called "hot."

In subacute rheumatism there is more or less acidification, but not to the extent observable in the acute variety; but the gastric and hepatic disorder is often much more manifest in the former than in the latter: this, again, is seldom, the other often, hereditary; this never becomes chronic, and generally leaves the patient as he gets older; the other is always prone to recurrence, to chronicity, and to aggravation in old age.

There is an obvious pathological relation between acute and subacute rheumatism; but still there are items which point out their distinctness, the chief of which is, that they do not run into one another.

The treatment of subacute rheumatism is not a matter of difficulty, except in so far as the task is often a tedious one. The indications to be fulfilled are both general and local. The former chiefly consist in improving the alimentary functions, correcting the secretions, and imparting tone to the system; the latter in soothing or strengthening, as the case may be, the suffering part. Let me recall to you some of the examples you have seen.

Ann Hacket, aged fifty-six, was admitted to hospital on the 6th of November last.

She was the subject of rheumatism in a subacute and severe form, which was of about five weeks' duration. She had often suffered from it before. The affected parts were chiefly the shoulders, back, and knoes. Her tongue was coated with a yellowish-white fur; appetite bad; bowels costive; urine scanty, and depositing a copious red sediment; saliva acid. She was ordered to put her feet, every night, into hot soda and water, and to take the following:—

R. Inf. gentiana comp., ʒviij.; sodæ bicarb. potassæ bicarb., aa. ʒij.; sp. eth. nit., ʒij. Misce fiat mist. cujus cap. coch. magna duo ter die. Cap. omni nocte, pil. rhei c. gr. v.

Under this form of treatment she immediately began to improve, and continued to do so, without one untoward symptom, until she was quite well. In this state she left the hospital in nine days after her admission.

In the same ward (the bottom one), and at the same time with this woman, was a girl, whose name I forget at this moment, the subject of very severe lumbago, caught by sitting on damp grass. She was ordered the same mixture as the preceding, except that infusion of calumba was substituted for that of gentian. This girl's stomach was rather irritable, for which reason I made the change. In gastric or intestinal irritability, calumba is one of the safest tonics you can give; it will sometimes arrest vomiting after other remedies have failed. The pain this girl suffered at night was so severe that I gave her five grains each of compound rhubarb and compound soap-pill. These procured her some slumber, and relieved her bowels without griping. Her back was ordered to be fomented with hot soda and water three times a day.

This plan soon began to prove successful, for a week had not elapsed before the girl could walk without assistance the length of the ward. It was a curious gait, you remember, but still she had not managed as much locomotion for some weeks prior to coming into the hospital. At the end of a fortnight she was so considerably better that her compound soap-pill was discontinued at night, and her alkaline fomentations in the day. In place of the latter, she was ordered an opium plaster, twelve inches by eight, across the loins; there was weakness of the lumbar muscles, but no pain. The tonic mixture was continued for another week, when there was no further use for it. The girl left the hospital in a few more days, in all respects well, except that her menses had stopped since her attack of lumbago. For this residuary ailment she took with her a bottle of æsquichloride of iron, of which she was to take twenty drops thrice daily. I requested her to call as an out-patient if she did not derive benefit from the drops, and she came in about a month, to say that there was nothing further of which she had to complain.

Jesse North, aged twenty-seven, was admitted into the top front ward on the 21st of January last, suffering from subacute rheumatism. He had been the subject of it for upwards of two months, a fortnight of which time he had been an out-patient; but I advised him to come into the hospital, for whilst he followed his employment (stage carpenter at the theatre) there was little chance of doing him any good. His pains were chiefly in his knees, where they were fixed, and somewhat severe; but he had also flying pains in his shoulders, elbows, and loins. There was little sympathetic fever, and the appetite, though not good, could scarcely be called defective. There was abundant lithic deposit in the urine, and the saliva and perspiration were very acid; the tongue was tolerably clean; there was little thirst, and the bowels were confined. He was ordered an alkaline bath at bedtime, and the following:—

R. Inf. buchu, ʒviij.; liq. potassæ, ʒss.; tinct. hyoscyami, ʒij. M. ft. mist. cujus cap. coch. ampla duo ter in dies. Cap. pil. rhei c. gr. v. omni nocte, hora somni.

With this treatment, he steadily improved until the 27th, when we found that he was suffering from synovitis in the left knee. In every other respect he was much better. I had not seen

him the day previously, but learned that, on the night preceding this, his knee had become uncovered whilst he was asleep, and exposed to a draught through a window near which he lay. The knee was largely swollen, immovable, and very painful, and there were evidences of fluid in the joint.

A blister, six inches by five, was ordered to be applied to the knee; the mixture to be continued; and the following pills were substituted for the compound rhubarb:—

R. Pil. coloc. c., pil. sapon. c., opio, aa. ʒss.; pil. hydrarg., gr. x. Misce in massam, dividendam in pilulas xij. quarum capiat ij. omni nocte.

From this time we had nothing to contend with but the trouble in the left knee; the other rheumatic pains were all gone. The inflammation in this joint, however, continued so obstinately that we were obliged to keep open the blister, and give occasional doses of calomel. It was not until a fortnight had elapsed since the occurrence of the synovitis that this could be considered to be fairly at an end. Even then, there was left considerable swelling, and, as a natural consequence, tension and weakness. The following medicines were then ordered:—

R. Inf. buchu, ʒviij.; liq. potassæ, ʒij.; hydriod. potassæ, ʒss.; sp. eth. nit., ʒij. M. ft. mist. cap. coch. ampla duo ter die.

R. Pil. rhei c., ʒij.; tinct. hyoscy., ʒj. Misce et divide in pil. xij. quarum cap. ij. omni nocte.

The knee was ordered to be well rubbed, night and morning, with this liniment:—

R. Liniment. sapon. comp., ʒij.; tinct. lyttæ, tinct. opii, aa. ʒss.; potassæ hydriod., ʒjss.

From this time the knee began to improve, as also did the patient's general health; and on the 27th of February, when his note had expired, he was dismissed well. For several days previously he had expressed a desire to return to business, but I prevailed upon him to remain in the hospital that he might further enjoy the advantages of rest and judicious living.

Synovitis is sometimes a formidable feature in the general progress of rheumatism. When very active, and marked by external heat and redness, local depletion by leeches is judicious practice; and the best plan is to bleed well at once, so as to cut short the inflammatory process. When this is less strongly shown, as in the last case, blistering is common enough, and the discharging surface may be kept open if necessary; it is always advisable to do this if there be any fear of accumulating fluid, or the continuance of low inflammation. Either may endanger the joint. Additionally, alkalis and gentle mercurials are valuable. After the subsidence of the active symptoms, preparations of iodine, generally and locally, are useful as agents of absorption.

Chronic rheumatism exhibits no particularities distinct from the subacute variety, except what may be considered the result of the long continuance of the disease. Chronic rheumatism, in fact, is nothing more than a persistent form of subacute. Various causes lead to this persistence. As people advance in life, their liability to rheumatism not only increases, but they lose the power of throwing off an attack. It seldom attains to anything like a crisis, but shows an atonic type, being better one day and worse another, but rarely ever becoming decidedly manifest, and as rarely disappearing altogether. Hence, this long-continued irritation weakens the vitality of the affected part, causes a thickening of its ligamentous or cartilaginous structures, lessens its circulation, and diminishes both its sensibility and motility. Thus, we find joints that have suffered from chronic rheumatism, thicker, colder, and less movable than natural. You saw an excellent example the other day in the person of a female out-patient.

We sometimes meet with chronic rheumatism of the most intractable kind, in adults, and even in young subjects who have passed the period of puberty. This is chiefly amongst those who inherit the rheumatic or scrofulous diathesis; who have become cachectic; have suffered much privation or exposure; or have been largely bled

of mercurialized. The abuse of mercury is a very prolific source of subsequent rheumatic seizures, which are generally severe in proportion to the impression made upon the system by the drug. It is in melancholy cases of this kind that you often meet with nodosity of the joints, periosteal and venous thickenings, and sometimes with *meta-paralysis* of the affected limbs.

The treatment of chronic rheumatism is both local and general, and mainly consists in imparting tone and energy to the system and the suffering parts; correcting any undue acidity; allaying pain by narcotic remedies; and diminishing the absorption of any materials that may be foreign to the joints, or unfavourable to their motion. These things are not usually difficult of accomplishment in young or adult subjects whose constitutions have not been utterly injured; but in advanced age, your chances of doing good are much fewer, and in many cases you are obliged to be content with only palliative measures.

Give me your attention now, gentlemen, whilst I dwell upon two cases of chronic rheumatism which you have seen treated at this hospital—one of them, certainly, as bad a case of the kind as I ever met with. This one was in the person of Edward Nello, aged thirty-one, who was admitted under my care on the 27th of February last. He occupied the top ward. The following is the history of his case:—

He had served for nine years as a private in the Dragoon Guards. He had enjoyed good health up to thirteen months prior to the date of his admission, when he was thrown by a young restive horse, and his back considerably bruised by the fall. This happened at Exeter, and in the regimental hospital of that place his injury was treated and considerably relieved. When convalescent, he caught a violent cold, and the pain in his back returned with great severity, additionally to which he had severe pains in his shoulders, hips, and knees. He was again treated in the hospital during the period of four months, but with little benefit. His joints, he informed me, were largely swollen, hot, and excessively painful, and the pain in his back was so severe that he could not support himself in the upright position. At the end of four months, the regiment came to Birmingham, and he was in the barrack-hospital here, under a fresh surgeon, for upwards of three months, but with little or no improvement. Subsequently, the regiment went to Chatham, and he was three months in the general hospital there; but, making no progress, he was dismissed as incurable, and on leaving the regiment, came to Birmingham to see some friends. When he had been here about two months, he was persuaded to come into Queen's Hospital.

When we first saw him (nearly all of you, I think, were present at my first interview with him) he had a very sunken, careworn look. His appearance was that of a man almost double his age. Face thin and sallow; limbs considerably wasted, except the elbow and knee joints, which were larger than natural, and somewhat tender on pressure. His legs he could not straighten, and said that he had not done so for more than a year; neither could he straighten his back, and the effort of attempting this caused him so much pain that the sweat actually ran down his face. The poor fellow, in fact, was seemingly crippled; he walked with the greatest difficulty, and could not conveniently hobble more than a dozen paces at a time. His pains during the night were so severe that he disturbed the other patients with his groans; and the nurse told us that he often cried bitterly when these pains were upon him. His tongue was pale and furred; appetite very bad; saliva acid; urine depositing a copious red sediment; bowels constive.

He was ordered an alkaline bath at bedtime, to be repeated every third night, and the following medicines:—

R. Infus. diosmæ ornatæ, 3℥ij.; liq. potassæ, 3j.; hydriod. potassæ, 3ss.; tinct. hyoscy., 3℥j. M. ft. mist. enj. cap. coch. larg. duo ter die.

Pil. coloc. c., pil. aspon. c., opio, aa, 3ss. et divide in xij. quarum cap. ij. omni nocte.

In two or three days from the date of this treatment he began to feel better, and to walk better. He expressed a hope that his leading wish would be gratified—to be reinstated in the army. In a week his improvement was so decided, that I felt inclined to change the opinion I had at first formed, that at best his treatment could be only palliative. When a fortnight had elapsed, you know we found him going through the different processes of drill, much to the amusement of the other patients. He then told us that, with the exception of pain in his back, he felt as well as he had ever done in his life. He could straighten his knees, and walk well; his appetite and general health were much better; he had scarcely any pains by night or day; his knees and elbows were less swollen; tongue clean; urine natural; bowels open. He was ordered to continue his medicine, to discontinue his baths, and to have applied to his loins an opium plaster, twelve inches by eight.

This was all the treatment the man had, until he had been in the hospital five weeks, when he caught cold one day, and had a slight attack of diarrhoea, but he had no return of his rheumatism. You remember how he used to show us his muscular capabilities, in testimony, not only of his improvement, but of his fitness to return to his ambitious position in the dragoons. He was in the hospital two months, and left it, to all intents and purposes, well.

As I have before said, this was one of the worst cases of the kind I ever met with; and certainly its recovery surprised me, as it did the poor fellow, who had often been told that he would never regain the use of his limbs. The alkaline baths did him much service; but I am inclined to attach the chief importance to the hydriodate of potass: this is of vast service in cases of this kind, and the more especially if you combine it with *liquor potassæ*. You may make any tonic infusion the vehicle, but I have a liking for bucha (perhaps because I am accustomed to it), for, in addition to tonic properties, it also possesses those of a diuretic and diaphoretic.

The next case I have to speak of, and very briefly, is the out-patient, Pearce, who visits us every Wednesday. He suffers from lumbago and sciatica. When he first came he could scarcely walk, and we learned that his ailment was of about eight months' duration. He was ordered the same mixture and pills as were given in the last case, and an opium plaster was applied to his loins. As you know, he began to improve from the date of his attendance, and the last time we saw him (six weeks from his first visit) gave us good evidence that ere long he would cease to be a patient.

The woman, Dale, in the top ward, came in a few days ago, recommended by the last patient. She has his identical ailment, of thirteen months' standing, but was at first more crippled than he was. Additionally to the medicines he takes, she has her back and hip fomented every night and morning with hot soda and water. She told me to-day that she had felt great relief from her treatment; and, indeed, seeing her up, and eating a tolerable dinner, gave me convincing proofs that her tale was true. I have no doubt that she will soon be well.

I have selected only a few cases to illustrate the treatment of chronic rheumatism. You have seen more than these treated in the hospital during the last eight months, and, without an exception, seen them successful.

In all these cases I advise you to push the alkaline treatment, both locally and generally: the hydriodate of potass is of vast service; bucha is a good vehicle, but you may give any other if you like; with old people *cascarilla* or *cusparia* is excellent, and the addition of ammonia is often valuable. Tincture of iodine to the joints, or hydriodate of potass ointment, composed of a drachm of the salt to an ounce of cerate, is a good remedy, when there is enlargement of the

proper structure, or nodosity. Alkaline fomentations generally do great good; and an opium plaster, where applicable, or tincture of acetate, is valuable in subduing pain. In old people, remember, your plan must be chiefly sustaining and palliative.

[ERRATUM.—At the close of the last paragraph but one of Dr. Wright's lecture, last week, there occurred a typographical error. In place of "the lithate of potass is less soluble than that of soda," read *more soluble*.]

A COURSE OF LECTURES ON SURGERY, BY

SAMUEL COOPER, Esq., F.R.S.

Professor of Surgery to University College, London;
Consulting Surgeon to London University Hospital, &c.

LECTURE X.

GENTLEMEN,—In the last lecture we considered the nature and exciting causes of suppuration in its progressive stages, and sooner or later it accomplishes a discharge of purulent matter, either from an abscess or an ulcerated surface. Before proceeding to the treatment of abscesses, it will be well to notice a little more particularly the nature and qualities of the discharged matter. Healthy pus, the fluid which comes away from a simple or phlegmonous abscess, or a common wound or ulcer, in a healing state, is of a thick creamy consistence, of a light yellow colour, sometimes approaching to green: these are the properties most obvious to the observer. It sinks in water, though, if shaken in that fluid, the latter remains turbid and thick; its weight is nearly that of blood. Under the microscope it is found to be composed of small white globules, floating in a fluid which coagulates with heat, from which it has been supposed by some to be the serum of the blood; from which, however, it differs in important particulars. The globules were supposed by Dr. Pearson to be those of the blood altered in colour in the process of suppuration. Gendrin, who, from the irregularities in shape and size, questions this, notices that the globules of the blood, in moving to the neighbourhood of the abscess, lose their distinctive colour and become globules of pus. In healthy pus the globules are more abundant: it is thus thicker and whiter than unhealthy; it has no smell, and is certainly not acid or corrosive, as it was formerly the fashion to describe it, nor does it irritate the surface which secretes it. When pus is discharged, however, from ill-conditioned sores or from some specific disease, its smell is offensive, and sometimes disgusting. That which comes away in gonorrhoea may be distinguished from all others by its peculiar smell; while that of cancer makes its presence known throughout the ward by its highly offensive odour. When, during suppuration, disease attacks the constitution or suppurating surface, a change takes place in the quantity and quality of pus secreted; true pus is no longer formed, the discharge is thinner, more transparent, and of fetid odour, and resembles more the nature of the blood: in this state it is termed *saniem*. This fluid is more disposed to putrefy, and may irritate even the suppurating surface. It has more of the serum, and often more of the coagulating lymph, which is probably present in all pus, and a greater proportion of those extraneous parts of the blood which are soluble in water. It differs, however, considerably, according to the nature of the disease producing it: phlegmonous and acrofulous abscesses, cancerous sores, and irritable ulcers, all differ very much in the quantities of their pus. It will be often seen that, where fever supervenes, pus ceases to be deposited during such disturbance, which returns on the diminution of such disturbance; and the same effect is produced by inflammation of neighbouring parts.

Erroneous views have been very prevalent as to the purposes which a discharge of pus subserves in the system: thus it has been imagined that bad humours are conveyed away by abscesses and ulcers, either from local or constitutional disorders. On this account other sores have been by various means induced, as a prevention, before drying up those which exist, and to become their substitutes in the same service. Of the true use of pus, however, we know very little, and the opinions I have just quoted become of little value when it is remembered that it is in healthy constitutions, and from healthy sores, that pus is formed most perfectly; and, provided such sores are not near the organs of life, they may be healed without any of those consequences which must follow if their existence were essential to the suppression of constitutional or local disorders. As supplying a means of communication between a disease and the outer surface of the body, and for the expulsion of foreign bodies, the usefulness of suppuration must be apparent.

When called upon to deal with suppuration in its earlier stages, you will have to form a judgment on the practicability of terminating it by resolution or absorption. As the methods to be taken are the same which have been directed for diminishing inflammation, I need not dwell upon it again at any length. When suppuration comes on, inflammation may be said to take a different form, rather than to be terminated; the excited action of the vessels has obviously not stopped; and, though the appearance is altered, the existence of inflammation must still be recognised. This remark applies particularly to the early stages of suppuration from acute inflammation, since, when an abscess has been burst for several days, its acute character may be said to have disappeared. When inflammation has decidedly led to suppuration, it may not be always the best course to repeat the same active antiphlogistic means as have been employed in the former stages of its progress; still it will be well to keep it in check by mild saline medicines, and careful abstinence from anything calculated to stimulate either the system or the part itself. If the pain, tension, heat, and redness be great, the application of leeches, supposing the general health is not low. If you cannot expect to terminate inflammation by resolution, you must make use of warm soothing applications to the suppurating part: these will, with mild medicines and rest, contribute greatly to a favourable result. Where the pain is severe, opium will be a valuable auxiliary. By treatment of this kind you will be using the most likely means to arrest suppuration and disperse matter when it has been deposited, and at the same time of successfully terminating where that course is not possible. With these measures you should also be careful to remove all sources of irritation: the exciting cause, as reason will tell you, must be removed.

When those symptoms of the formation of pus—fluctuation and pointing—which were noticed in last lecture, present themselves, it is a rule in surgery to make an early opening, in order to free the part from the irritation arising from tension and pressure, which may often increase the inflammation itself. Where the system is very low and inflammation reduced, an abscess is more likely to be displaced, in consequence of the action of the absorbent system; and, by stimulating the various secretions, that pus which is deposited near the absorbent glands will be sometimes dispersed. Although, in practice, the time when any particular abscess should be opened is a matter for the individual judgment of the surgeon, yet there are certain circumstances, under which all surgeons agree they should be opened, when the fact of the formation of matter is well ascertained. Of these abscesses from acute inflammation, seated amongst adipose and loose cellular membranes; in these, unless provision is made for the escape of the confined matter, sinuses may follow; also where urine, fecal matter, or other stimulating fluid, is extravasated in the cellular tissue,

where they are formed under thick fasciæ, or under sheaths of tendons, as under the fasciæ of the thigh, or which contain dead bone, where the matter is in danger of making its way into the chest or abdomen, they should be opened early. Abscesses, also, under the sterno-cleido-mastoid muscle, in the cellular tissue separating the muscle from the parts below, and others near important organs producing great functional disturbance by pressure, as near the neck of the bladder, or near the larynx, trachea, or œsophagus, or other organs. When the matter of an abscess lies close to a bone, it should be opened immediately. So, also, chronic abscesses should not be left, because they may be a long time in bursting, and, for want of opening, will extend.

You will find of the two methods of opening an abscess, by a cutting instrument or by caustic, the former is to be preferred: not only is less pain inflicted, but the end is gained more expeditiously; and, as the texture is only divided, not destroyed, a smaller cavity is left; the outlet may also be made more conveniently, according to the intentions of the surgeon. The use of caustic is now almost confined to those cases in which a permanent opening is required: it is too slow and ineligible a mode to become general—wanting the precision of the cutting instrument. Of these the best, except when only a small opening is required, is the double-edged bistoury; when it has been inserted into the tumour, the size of the opening can be easily increased by moving the edge forward. In determining where to make the opening, you will be guided generally by the presence of fluctuation in a particular part, and by the thinness of the skin: at the same time, you must consider such locality with reference to the facilities which it may give for the escape of the matter.

Sometimes, when the abscess bursts at a point not favourable for the emptying of the tumour, you must make a counter-opening. In such cases it is better to cut through a certain thickness, than allow it to burst at its point. After opening abscesses it is necessary to maintain, &c., i. e., to prevent the healing of the wound till the cavity is so far reduced as to prevent another accumulation of matter in the same cyst; but this is not always advisable. After the opening of an abscess, the sides of the cyst are gradually (it is not necessary to squeeze out the contents, nor to place lint in the cavity) drawn towards the centre, and are at length obliterated. Some, however, will not heal, but after having been open for some time, from some cause keeping up suppuration—which may be the presence of a foreign body, the position of the abscess, disturbance from neighbouring muscles, or one of many other kinds of excitement—form a fistula. You are in all such cases to inquire what is the exciting cause, and to aim at removing it; and also to make a freer and more direct opening. After the opening of the abscess, the emollient applications are to be discontinued, and common dressing and a bandage put on.

I mentioned to you, that on the bursting or opening of an abscess, there is frequently a change in the constitutional disturbance, much pus is discharged, and the patient is brought very low; hectic, the leading features of which are prostration of strength, with weak pulse and nocturnal exacerbation, comes on; the patient then requires tonic treatment and a more invigorating diet.

It is proper that I should say a few words about this fever: it is distinguished from the symptomatic fever which takes place as the immediate consequence of local irritation upon a healthy constitution. Hectic fever is the remote effect of a local injury on an exhausted constitution unable to react and successfully to struggle against the local evil. It is more chronic in its character, and marked by a state of the pulse, often very significant. A person has a chronic abscess; there is no external local sign, but matter is, nevertheless, forming; and the observant surgeon may often discern its existence by the quick and sharp pulse, the loss of sleep

and appetite, and night sweating. Where the disorder is more established, the pulse becomes smaller; it is quicker towards evening, reaching as high as 120, and sometimes higher than this, and always exceeds the customary healthy rate by twenty strokes a minute. The skin is moist; the urine pale and abundant, with sediment; sometimes vomiting, great flushing of the face, heat of the soles of the feet and the palms of the hands. At a more advanced stage, the night sweats are more profuse, and the evening exacerbation increases; and in the latter stage there is a tendency to diarrhœa. It is observable that when diarrhœa comes on the night sweats disappear and are seen no more.

The surgeon, in this disease, if unable to remove the exciting local cause, cannot be certain of success; he may, however, alleviate the pain, and in so doing he will give the best chance of recovery. If the diseased part can be removed by operation, and the system will bear it, there is hope, and a pure air and nourishing food, easy of digestion, wine and gentle cordials, with opium, bark, and steel medicines, are indicated for maintaining the constitution during its struggles. Hectic comes on quicker in proportion to the nearness of the local irritation to the vital organs. Such sources of irritation often causing hectic when situated in more remote parts of the system, they would be of small consequence: if you can remove the local cause of irritation, the hectic will subside. John Hunter takes notice of this fact, and I remember having seen several joints removed when the patients were in the last stage of hectic fever; the pulse has fallen from 120 down to 50 strokes a minute, and the patient has slept the first night without pain. I have seen patients brought into the operating-room fainting with disease, perhaps of the knee or some other joint, and the comfortable night which has succeeded the operation has confirmed the correctness of John Hunter's remarks.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILSHIRE, M.D. (Edin.), M.B.S., Physician to the Royal Infirmary for Children, &c. &c.

(Continued from p. 309.)

In my lecture to-day, gentlemen, I shall conclude what I have to say upon scrofula, in applying the general principles I have given you to the more important divisions I before made of scrofulous disorders. I cannot but feel I have detained you a long time upon our present subject, but its great importance is my best apology for having done so.

Suppose a scrofulous child is brought to you, evincing both by the *artistic* characters and such local signs as enlargement of the lymphatic glands, chronic eczema, &c., that it is scrofulous; but yet not presenting evidences of tuberculous deposit or active inflammation anywhere, you have to find out if the little patient be living in a great town and wants the hygienic influences I have already recommended. If so, the child is, if possible, to be removed to the country and at once put under them. If this removal cannot be accomplished, you must make the best shift you can in the place it lives in. The bowels are to be gently relieved by the use of rhubarb and soda, or, if the dejections be very pale or there is hepatic fulness, a small dose of hyd. c. crota or calomel may be added to the former for two alternate nights, the belly being rubbed with a turpentine or stimulant embrocation; sometimes you will have to follow the above with *cutor oil* in the morning. If there is not much debility, the iodide of potassium is to be given alone; if the reverse, combined with quinine, and these in doses graduated to the age. In infants, weaning the child and giving it the wine of iron, will sometimes be the best. In girls between ten and fourteen, if there be much pallor of the face, the sesquioxide of iron in teaspoonful doses may be administered twice a day in treacle. In some

cases, where the cutaneous surface is affected, I have found that the bichloride of mercury in the compound tincture of cinchona will cure that in which the iodide has been unavailing; the dose will vary from one-sixteenth of a grain to one-eighth, three times a day. If the bowels become irritable under this agent, you must suspend it and give a mild narcotic and foment the belly. Very often, during the period in which such a child is under treatment for scrofula, remittent fever or some form of stomatitis makes its appearance; you must then suspend your present remedies, and give the nitrate of potash or some other saline; and, if stomatitis is present with the former, you will find nothing so useful as the chlorate of potash, and borax locally employed to the oral cavity. For children weak in the loins, &c., recommend the dashing at first of tepid salt water, then of cold, forcibly over the lower portion of the body, and the frequent use of stimulating embrocations. Of the proper diet, &c., I have already amply spoken; of any local measures to be adopted to swollen glands, skin eruptions, I shall speak of presently.

Suppose you have to deal with a scrofulous child in whom there is tuberculous deposit and its changes going on, or there is an advanced state of the disease of the cancellated tissue of the osseous system. You have now to call into requisition not only great judgment in treating the constitutional disorder, but also in mitigating the local affection, which of itself is often sufficient to produce the death of the patient, and in fact, in some cases, we can alone pay attention to the local manifestations: so important and urgent do they become in spite of what may be said of never losing sight of the diathesis producing them. The general symptoms we have to attend to are additions only to those we are endeavouring to combat when tubercular deposit has not ensued, viz., emaciation, debility, and fever: for let tubercularization in any visceral organ progress, or disease of the bones make way, and we shall have hectic with all its attendant train of phenomena. The same hygienic principles are here, of course, to be enforced as before; but unfortunately, in the more advanced stages of the disorder, neither the stomach will bear the food or the appetite demand it, nor will the bodily powers permit of that exposure to air, &c., which otherwise would be so recommendable. Whatever organ indicates there is tuberculous disease going on, I know of no symptom in the earlier stage prohibiting the iodide of potash, and quinine, save nausea and irritability of the stomach; and therefore you may follow the treatment before recommended. Magnesia and hydrocyanic acid in cinnamon or caraway water, or in infusion of calumba, may be employed to mitigate the latter troubles; and the addition of a mustard poultice to the epigastrium, or the use of a strong embrocation there, will be useful resources. If the meninges be the structures attacked, the quinine should be omitted, and small doses of iodine given with the iodide of potash; the head being shaved, rubbed well with the compound iodine ointment, blisters applied over the mastoid processes, and the bowels freely opened. In this form of the disorder the iodides of mercury have been considered by some to be of considerable service. If the peritoneum or mesenteric glands be attacked, foment the belly well, have it rubbed with the compound iodine ointment, and give the iodide internally. Often iron will be very useful here. The state of the bowels—very various in this form of the disease—will indicate other therapeutic measures to be adopted. When the joints or spine are involved, the iodide, with quinine or iron, are the internal agents to be adopted.

In tuberculous, when advanced, the treatment of particular symptoms becomes very important; and whether the disorder takes on the acute, chronic, or latent type requires to be considered. I cannot agree with those who state that in acute tuberculous, or when hectic commences in the very early stages, loss of blood is advisable: I am aware some high authorities

support this doctrine, as for instance Sir J. Clark, Rilliet, and Barthez, but I think the more direct and powerful antifebrile measures, such as antimony, nitre, &c., are the utmost that we can fall back upon; and I may tell you that antimony has a very powerful, depressing effect on a child. To check diarrhoea, chalk mixture with aromatic confection and tincture of catechu, or mucilage with the acetate of lead, may be given even to very young children. In many cases you must give them opium, but of course in carefully regulated doses.

The acetate of lead often has the power of checking the perspirations as well as the diarrhoea; but the former, when the bowels are not too irritable, may be treated with the mineral acids and a sedative.

The next group of cases I have to allude to are those in which intercurrent attacks of inflammation take place in the course of the tuberculous malady. These attacks may involve the tuberculous organ, or another not so affected. You must remember that when inflammation invades an organ already having tubercles deposited in it, or when it attacks, we will say, the peritoneum, the deposit being in another structure, you have two elements to deal with—the one the inflammatory, the other the tubercular. In all individuals these two elements are not in an equal ratio: for in some the inflammatory action follows much the course of a primitive inflammation—the tubercular being only presumed to exist; whilst in other cases there is no doubt about the tuberculous, and the inflammation is of a chronic or, if I may so call it, of a very unobtrusive character. Whether the peritoneum, meninges, &c., suffer an intercurrent inflammatory attack, general bleeding is not to be had recourse to: for admitting that the inflammation might, in some instances, be reduced, the increased debility arising from the loss of blood would still further promote the progress of the tubercular malady. In such cases, too, as where the meninges are involved, all the bleeding possible would not put a stop to the local circulatory excitement. Loss of blood, by cupping in older children, by a leech or leeches in younger, is the only proper way of diminishing the amount, &c., of the circulating fluid, when such is needed. In these cases blistering is often exceedingly apposite, if the child be not very young; otherwise mustard poultices and stimulating liniments are to be employed, or friction with the compound iodine ointment.

Such are the principles which are to guide you in the more constitutional treatment of the great groups of scrofulous disorders, but which I shall speak of more fully when I touch upon the particular maladies themselves.

A very great importance attaches, in my opinion, to the local treatment of some of the varieties of scrofula, inasmuch as, by a judicious application of remedial agents to the parts affected, the constitutional powers, which we are attempting to influence at the same time by general measures, are much assisted in bringing about a cure of the local affection.

In all cases of glandular enlargements, or indurations of the cellular tissue, there is no necessity—on the contrary, the reverse—that the suppurative of such should be cut off or hastened, as is often desirable when such enlargements occur in a different constitution. If the enlargements are small in size, and not firmly adherent one gland with another, or with consolidated cellular tissue, it is better to leave them alone whilst the system is being affected with internal remedies. If, on the other hand, the glands are hard, consolidated, and much enlarged, but not presenting external appearances of much inflammation, you can do nothing better than rub in the compound iodine ointment, night and morning. Whether the patient be two or fourteen years of age, this ointment best answers the purpose. I never find it too strong for the youngest children, if not rubbed in too vehemently and roughly; but of course according to the natural delicacy of the skin, so will be the degree of ex-

ternal irritation it produces: sometimes that is considerable, at others nothing at all. If the glandular enlargement is very tender to the touch, red upon its surface, or soft towards the centre, poultices should be applied for a short time, when, if the irritation subsides, the previous treatment is to be adopted. If, however, it continues, or the part becomes redder, more tender, and softer at the centre, the poultices are to be continued, and matter evacuated when any quantity has been formed. The latter advice applies to abscesses generally; in the scrofulous constitution, never allow matter to accumulate—never think of its removal by absorption. After the collection has been opened at its most depending portion by the knife, not caustic, continue the poultice for a day or so, and then use warm-water dressing, the lint having a few drops of the tincture of hyoscyamus or hemlock put upon it if there be much irritation. Do not continue warm applications too long—you will debilitate the part; and you will find a lotion made of the sulphate of zinc in rosewater much better.

The edges of the wounds, or the sinusses which may form, are often materially benefited by painting them with the tincture of iodine, but lotions of the sulphate of zinc, of copper, or the nitrate of silver, will do much to ensure their healing; when practicable, a compress dipped in the lotion, and applied with a bandage to effect pressure, is very useful. I would recommend you not to use the so-called evaporating lotions to these affections, and I cannot say I have seen that advantage from salt and water which some persons state they have.

In the chronic affections of the cutaneous surface, while internal treatment is being adopted, lotions of zinc, copper, or silver, painting the part with the tincture of iodine, after incrustations have been removed by poultices, &c., or applying the solid nitrate of silver, will generally answer the purpose desired. But these affections, under any treatment, you know well enough, are often exceedingly obstinate to cure.

In inflammation of the mucous membranes stimulating and astringent lotions are better than anything else. Those of the metals I have before spoken of answer very well, and may be applied to the eye, snuffed up the nose, and injected into passages, as the case requires. I have found a lotion of the tincture of the sesquichloride of iron very serviceable in the chronic vaginitis of female children.

Whilst you employ the lotion to the eye in conjunctivitis, you will find that a blister placed behind the ear will facilitate the cure; and you must not allow the patient to be kept in a dark chamber, or wear a large shade. Sometimes the nitrate of mercury ointment with triple its quantity of lard, so as to make it equal to the diluted ointment of the Edinburgh Pharmacopoeia, may be placed between the eyelids on going to rest. If there is inflammation of the Schneiderian membrane, which keeps up the irritation in the visual apparatus, the former must be subdued by the application of one or other of the lotions I before recommended.

In otitis poultices to the ear, or blisters behind it, with gentle injection of tepid water, are most serviceable. I do not much like attempting to put a stop to the discharge by astringent or stimulating injections here.

In cases in which disease is going on in one of the visceral or internal structures, the compound iodine ointment is to be freely rubbed over the part. It may be applied to the shaven scalp, abdomen, chest, between the shoulder blades, or applications of turpentine, mustard, &c., may be now and then advantageously employed, as also warm sedative poultices and fomentations.

If you have a case of disease of the knee joint to attend to, take care that you lose no time in attacking it. At first blister the part on each side alternately, beginning a little lower down than the centre of the patella, by means of the strong solution of iodine I have before recommended; you may, if you like, use the solid nitrate of silver to effect this purpose. But I think you will find the other very advantageous. In a case

which I am at present attending, and which has the advantage of the advice of Mr. Liston, this application has been found of great avail in allaying the pain and swelling of the joint, and, I believe, that eminent surgeon has had much experience in its use. This treatment should be continued for a fortnight, and during the time the patient is to be confined to the sofa, a paste-board splint being placed beneath the joint so as to prevent motion of it. Afterwards wash it well with soap and water; cover it with soap cerate, and apply pressure by strapping and bandages. Then apply lateral leather splints so as to keep the joint immovable, and send the child out into the open air to hobble about with a stick.

If the disease continue to progress, inflammation externally making its appearance, and matter forming, the pressure must be ceased, and poultices applied. The matter should be evacuated by a small puncture. As long as much discharge takes place, or the integuments keep inflamed, the poultice or warm-water dressing is to be continued; but as soon as they diminish, gentle pressure is to be again had recourse to. If you are fortunate, even after the disease has made great progress, a cure may be accomplished by means of ankylosis; if not, measures must be adopted which do not become me to dwell upon, and for them I must refer you to authorities definitely surgical in their character.

In disease of the spine the counterirritation of caustic issues, I think, you will find the better mode of answering some of the indications, as, also, in disease of the bones of the hip-joint. In all cases of disease of the cancellated tissue of bone the lungs should be carefully examined, since in those cases demanding the severest form of surgical interference much will depend upon the state of these organs as to whether it can be adopted.

DUMAS ON ORGANIC CHEMISTRY. No. XXIII.

(Continued from page 290.)

INTESTINAL GASES.

Commencing the examination of the intestinal gases with those which exist in the stomach, we here usually find mere air, which the animal swallows during deglutition; but, in a short time, a portion of the oxygen of this air is absorbed, and in the small intestine we find the nitrogen alone, to which are subsequently added carbonic acid, hydrogen, carburetted gas, and remarkable quantities of sulphuretted hydrogen. In the normal state, that is to say, in the sound animal, the intestinal gases are never very abundant; but their quantity augments greatly under weak digestions. The kind of food has a great influence over the production of these gases, which always arise, in the small intestine, from the spontaneous decomposition of the aliments. If leguminous substances be eaten, which contain a large quantity of sulphuretted matters, we shall quickly find an abundant production of sulphuretted hydrogen in the intestine.

The digestive tube of the living fetus contains no gas.

Below are some analyses published by MM. Chevreul and Magendie, giving the constitution of the gases contained in the intestines of four executed criminals.

1. The digestive tube of a young man, twenty-four years of age, who had taken, two hours before his execution, some bread and cheese with water, contained:—

	Stomach.	Small intestine.	Large intestine.
Oxygen	11.00	6.00	0.00
Carbonic acid	14.00	24.39	13.50
Hydrogen	8.65	53.33	4.47
Nitrogen	71.45	20.08	52.03
	100.00	97.80	100.00

2. The intestine of a young man, twenty-three years old, who had made the same repast as the preceding, contained:—

	Stomach.	Small intestine.	Large intestine.
buttle of gas, which could not be examined.			
Carbonic acid	40.00	70.00	
Hydrogen gas	51.15	11.60	
Nitrogen	8.85	18.40	
	100.00	100.00	

3. Lastly, in the viscera of a subject, twenty-eight years of age, who, four hours before his death, had eaten some bread, boiled beef, and vegetables, and had drunk a little wine, there were found:—

	Small intestine.	Cæcum.	Rectum.
Carbonic acid	25.00	12.50	42.86
Hydrogen gas	8.40	7.50	0.00
Carburetted hydrogen	0.00	12.50	11.18
Nitrogen	66.60	67.50	45.96
	100.00	100.00	100.00

Professor Jurine affirms that the quantity of carbonic acid is greater in the stomach and small intestine than in the large intestine, and, on the contrary, that the latter contains more nitrogen than the small intestine and stomach—a result which does not altogether accord with the experiments of MM. Magendie and Chevreul. The observations of Jurine were made upon the body of an idiot who was frozen to death, and opened immediately afterwards.

Vauquelin analyzed the gases arising from some diseased animals, when dead; they contained a large quantity of carbonic acid, carburetted hydrogen, sulphuretted hydrogen, and a slight quantity of air.

If cows are suffered to graze in damp clover fields, we often see them quickly swell up, or even die, unless immediate aid be afforded. This disease, which is known by the name of meteorization, has been closely investigated by MM. Lameyron and Frémy, as well as by M. Plüger. It seems to be invariably due to a large development of gas which takes place in the stomach of these animals.

MM. Lameyron and Frémy analyzed the gases, which they procured by puncturing a cow in an extreme state of meteorization. The following was their composition:—

Sulphuretted hydrogen	80
Carburetted hydrogen	15
Carbonic acid..	5
			100

Should the gases accumulated in the intestine present the foregoing composition, we have recourse, for the relief of the animal, to caustic ammonia mixed with water. A drachm. of ammonia and four ounces of water are sufficient for this purpose.

M. Plüger also examined the gases derived from two meteorized cows. They exhaled a tainted odour, but did not contain sulphuretted hydrogen. Three fifths of the gas contained in the stomach of one of these cows were absorbed by lime-water, which was rendered cloudy; the remaining portion was composed of oxide of carbon. With the second cow, one fifth of the gas only was absorbed, the remainder being in like manner formed of oxide of carbon. We can at once understand that, in such a case as this, we must have recourse to puncture, as the only means of relieving the animal.

MILK.

We have already given a history of the principal materials composing the milk, and we have found this secretion in the herbivora to be characterized by the presence—1, of caseine; 2, of the fatty matters which constitute butter; 3, of a saccharine matter; 4, of a certain quantity of salts, variable under many circumstances. Let us now consider this fluid in its general characters.

Viewed as the chief aliment of young animals milk has deservedly attracted the attention of physiologists; it, in fact, constitutes the most perfect food, since it suffices for the development

of the animal, by furnishing to it organizable azotized matters capable of producing all the issues of the economy: the calorific aliments, as utter and sugar, and, also, the salts necessary for the development of the osseous frame.

But the interest which attaches itself to the study of the milk augments still more, should we seek to give an account of its production, in whatever point of view this may be presented to us. The milk is secreted by the teats of the female mammifera, towards the end of gestation and after the birth of the young. It is an opaque fluid of a characteristic pure white; when healthy, it is constituted of a solution of caseine, lactose, and salts, in which float isolated and perfectly circular globules of fatty matter; it forms a true homogeneous emulsion, very liquid and mobile. These globules of fatty matter do not present a constant diameter even in the same milk; with much greater reason, therefore, will they be found to vary in the different species of animals. This diameter has wide limits; still we may admit, as a mean calculation, that it is comprised between one and three hundredths of millimetre for most kinds of milk. The globules of the milk in the human female are, in general, according to M. Simon, larger than those in the milk of the cow.

Two very different opinions have been promulgated as to the physical constitution of the fatty globules of the milk. Some physiologists suppose that the fatty matter is enclosed in an albuminous cellular envelope, analogous to the membranes of the adipose tissues. MM. Raspail, Tenle, and F. Simon are of this opinion. Others believe that the fatty globules float perfectly free in the milk, similar to what occurs in emulsions.

This latter opinion is founded on the fact that, in the operation of churning, some time before the complete separation of the masses of the butter, we see the globules run one into another, and, in proportion as the operation advances, these give birth to still larger globules, which eventually form broad layers of fatty matter. Another circumstance is cited in support of this view: when we inject milk into the blood of an animal we may, by means of the microscope, readily distinguish the globules of milk from those of the blood into which it is injected; after a few hours, the former are found to run together in greater or less number, and over them a gelatinous membrane is formed, which eventually becomes very visible, from the circumstance of its having a refractive power different to that of the liquid mass itself. Now, M. Ascherson has observed, that, when we drop a little oil into any albuminous liquid, the oleaginous particles are quickly surrounded by a species of membrane of this kind.

But if the ready agglomeration of the globules of the butter, under the influence of churning or under that of the circulation, tends to make us regard them as deprived of all covering, there are other considerations which lead to a totally opposite conclusion. In fact, if the fatty globules which float in the milk were free, we should have merely to agitate the milk with ether to separate them from it; but nothing of this kind occurs; and, after even a prolonged agitation with this fluid, we find the milk remain perfectly opaque. If, however, we add to the milk a few drops of concentrated acetic acid, and then carry the mixture to the boiling point, so as to dissolve all the caseum which it may contain, we quickly see the globules of butter enlarge, as though several of them became joined together to constitute these great fatty drops. Moreover, the liquor, if now agitated with ether, becomes deprived of the whole of its butter. In addition to this character, which in itself leaves but little doubt as to the existence of an envelope around each globule of the butter, we may cite the effect observed on adding to the milk a saturated solution of sulphate of soda or of chloride of sodium. These neutral salts give to it the power of filtering, by leaving on the strainer the whole of the fatty globules, whilst the soluble caseum, the sugar of the milk, and the salts pass through in the clear solution.

Without affirming such a thing to be impossible, I may state that I have not yet been able to deprive the butter, left on the filter, of the whole of its caseous matter, by prolonged washings in saline water—a fact which would accord with the supposition of the existence of an envelope around the fatty globules.

Authors are not agreed as to the reaction which is presented by fresh milk, when brought into contact with litmus-paper. It appears that the milk, which is alkaline at the moment when it is withdrawn, may become acid in the air, in a very short time. D'Arcet and Petit have found it sometimes alkaline, and at other times acid, in the cow; it is alkaline when the cows are at pasture: acid, when they are kept on dry fodder in the stable. The milk in the human female is always very alkaline, and it appears to preserve this property so much longer, as it proceeds from a sound and vigorous woman; it quickly acquires in the air an acid reaction, when derived from unhealthy women.

The milk of the ass, when recently drawn, should, according to M. Peligot, be acid; according to other observers, it is alkaline; in all cases it becomes so, when we administer bicarbonate of soda to the animal. When left in the air for some time, the milk invariably becomes acid; this acidity is due to the spontaneous fermentation of a little lactic acid.

The density of milk is variable: that of cow's milk most frequently ranges between 1.030 and 1.032. The following is the density of various milks, as calculated by Brisson:—

Woman	1.0203
Mare	1.0346
Ass	1.0355
Goat	1.0341
Ewe	1.0409
Cow	1.0321

It is a very difficult matter to give the mean of density for a liquid, which may be modified by so many circumstances; in fact, we have merely to call to mind that the fatty substances are lighter than water, while the solutions of salts and of saccharine or caseous matters are heavier, to understand that the density of the milk may vary according as its richness in butter, in caseine, or in salts, augments or diminishes, and that it may remain stationary in spite of considerable changes, if the soluble products diminish at the same time as the butter, or vice versa.

When subjected to ebullition, milk does not coagulate; it becomes covered over with membranous pellicles, which may be readily removed, and which constitute the cream.

We shall shortly see under what circumstances it is that fresh milk becomes coagulated. In a chemical point of view, milk presents an admixture of all the properties which belong to the organic matters which enter into its constitution; it would therefore be useless to dwell any longer upon this point. All the acids coagulate milk, by precipitating the caseine, which draws with it the fatty matter; such is the mode of action of acetic, lactic, hydrochloric, and sulphuric acids, &c.; we have merely to heat the milk to about 75° C., to effect this change. A few drops of acid are often sufficient to coagulate a considerable quantity of milk.

The milk of the human female, which, as we have already stated, is distinguished by a very marked alkalinity, presents to us in this regard a peculiarity which is offered by none of the other milks hitherto examined. In fact, when we wish to coagulate the milk of woman, we must commence by mixing it with half of its volume of alcohol, and afterwards add to it a few drops of sulphuric acid; without these precautions, it simply acquires a peculiar viscous condition, different to what it previously possessed.

When left to itself in a suitable cool place, milk, after the lapse of about twenty-four hours, separates into two distinct layers: the first, which we denominate *cream*, floats on the surface; the second has received the name of *skimmed milk*. The fatty globules, being specifically lighter

than the liquid on which they float, are collected together at the upper part of the milk, and these constitute the layer of cream, which has a beautiful yellow colour, and which is principally composed of the fatty matter; this layer eventually becomes more and more homogeneous, in proportion as the greater part of the serum separates from it. This latter, however, still retains a considerable quantity of butyrous matter.

If preserved for a still longer time, milk finally becomes strongly acid, and coagulates. This phenomenon is due to the spontaneous production of a certain quantity of lactic acid, which reacts on the caseine and precipitates it entirely. Lactic acid is invariably produced as the result of a special fermentation, which MM. Boutron and E. Frémy have recently studied with great care.

This property of milk is then referrible to the varied phenomena of fermentation. M. Gay-Lussac has, in fact, shown that, as in the fermentation of the juice of the grape the air intervenes by exciting the formation of the alcoholic ferment, so, also, does it aid in the formation of the ferment which produces lactic acid. We may, in fact, preserve milk for several months, if it be boiled every day; in this manner we drive away the air which it may have absorbed and so prevent its coagulation.

D'Arcet has endeavoured to retard the coagulation of milk, which is consumed so largely in Paris, and which is especially liable to this change in summer; he advises the addition should it have to be transported any distance, of 1-2000th part of its weight of bicarbonate of soda the harmlessness of this salt permits its being employed to great advantage.

The spontaneous coagulation of the milk is owing to the lactic fermentation; but this quickly becomes in itself an obstacle to its continuance, and should we wish this fermentation to persist we must neutralize by bicarbonate of soda the acid which is produced. This salt, by rendering the caseum soluble, disposes it to act as a lactic ferment. But, if we allow the acid reaction to continue, the fermentation assumes another character: we observe a disengagement of gas, and alcohol is produced.

We have long known that the Tartars convert mare's milk into a spirituous liquor, from which they extract alcohol by distillation. The following is the way in which they proceed:—The vessel in which the operation is effected is made of the untanned hide of the horse, but which has been thoroughly hardened by smoking. Its form is conical and somewhat triangular. It appears to be composed of three pieces attached to a circular base. It is into this species of bag that they introduce the milk which is to be acted on; the vessel is about three parts filled, and its orifice closed with a flat piece of leather. It is to be shaken several times in the day, and uncovered from time to time. After the lapse of a few days, the milk will have acquired a vinous odour and taste. The agitation is continued until the acidity has become very marked; before long, however, this sourness will be found to diminish; the liquor is then decanted to separate it from the pasty matter which is deposited, after which it is poured into other bags and used as wine.

This mode of proceeding is not the only one adopted by the inhabitants of the various countries of Tartary. Sometimes, they merely add a little sour milk to that in which they wish to excite the fermentative action; or else they pour fresh milk upon the *magma* which constitutes the residue of a previous fermentation; others, again, add to the milk some sour paste formed from the meal of barley or of oats.

Parmentier and Deyeux have examined the products of the spontaneous fermentation of the milk of the cow, and they have proved the alcoholic nature of this fermentation by collecting the carbonic acid and isolating the alcohol. Scheele had previously observed the disengagement of carbonic acid. Lately, M. Hesse has been engaged in similar observations.

If we leave the alcoholic liquor in contact with

the air, the fermentation again changes in nature: an absorption of oxygen takes place and we have formed acetic acid. Scheele had proposed to apply this property of milk to the manufacture of vinegar. By adding a spoonful of spirits of wine, containing fifty per cent. of alcohol, to the *litre* of fresh milk, we obtain, according to the above author, in the space of about a month, a liquor charged with acetic acid and free from lactic acid.

ORIGINAL CONTRIBUTIONS.

ON THE PHYSIOLOGICAL AND PATHOLOGICAL CAUSES OF SUDDEN DEATH IN CONNECTION WITH THE VASCULAR OR CIRCULATORY SYSTEM.

By M. W. HILLES, Esq.

(Continued from p. 194.)

It is not a little remarkable that rupture of the heart is an extremely rare occurrence. Although the term *broken or ruptured heart* is frequently to be met with in common conversation or in writing, there is no part of the vascular system less liable to be broken or ruptured than the heart. This term must be regarded, therefore, as without much foundation; and as a figurative expression, used by society to indicate disappointed feelings, the seat of which is supposed to be the heart, although it is quite unnecessary to state that few of the passions, &c.—referred to this origin—such as love, grief, hope, &c., have any relation to it whatever.

That the more acute passions or feelings of man do produce uneasy sensations referrible to the region of the heart cannot be questioned; but this arises from this organ being the centre of the circulation, and, therefore, most liable to be implicated in all derangements which may affect the regular flow of the vital fluid, disturbed through the sympathy which exists between the nervous and vascular systems—two of the great vital centres—in the former of which only the various passions can be supposed to reside.

Instances, however, of ruptured heart are not wanting; some very remarkable public characters have died from this disease: Philip V., of Spain, amongst others; George II., of King of England, and the Princess of Brunswick, one of his relatives. Talma, the celebrated French tragedian, also laboured under a disease of the heart, which would in all probability have ended in a very short time in death from rupture, had not another disease induced a more rapidly fatal termination.

The sudden death of George II., of England, is thus related:—(a)

“Smollett, in his ‘History of England,’ vol. v., p. 418 *et seq.*, thus writes:—

On the 25th day of October, 1760, George, King of Great Britain, without any previous disorder, was, in the morning early, seized with the agony of death at the Palace of Kensington.

“He had risen at his usual hour, drank his chocolate, and inquired about the wind, as anxious for the arrival of the foreign mails; when he opened a window of his apartment, and, perceiving the weather was serene, declared he would walk in the garden. In a few minutes after this declaration, while he remained alone in his chamber, he fell down upon the floor; the noise of his fall brought his attendants into the room, who lifted him on his bed, when he expired, in a faint voice, that the Princess Amelia might be called; but, before she could reach the apartment, he had expired. An attempt was made to bleed him, but without effect, and, indeed, his malady was far beyond the reach of art: for, when the cavity of the thorax was opened, and inspected by the surgeons, they found the right ventricle of the heart actually ruptured, and a great quantity of blood discharged into the pericardium, so that he must have died instantaneously, in consequence of the rupture of the heart.”

(a) Elliotson's “Lectures on the Heart,” p.

quence of this effusion. The case, however, was so extraordinary that we question whether there is such another instance on record. A rupture of this nature appears the more remarkable as it happened to a prince of healthy constitution, unaddicted to excess, and far advanced beyond that period of life when the blood might be supposed to flow with a dangerous impetuosity.

Dr. Smollett's remarks, as to there being no similar case on record, is the more remarkable, as the Princess of Brunswick, a near relative of George II., died of the same affection in the year 1730; (a) and several similar instances are on record.

Dr. Nicholls's account of the *post-mortem* appearances of George II. may not be uninteresting:—"The pericardium was found distended with a quantity of coagulated blood, nearly sufficient to fill a pint cup; and, upon removing this blood, a round orifice appeared in the middle of the upper side of the right ventricle of the heart, large enough to admit the extremity of the little finger. The ventricles were found devoid of blood, either in a fluid or coagulated state."

We may be allowed to remark on the great liability to disease of the heart which appears to have existed in most of the branches of the present Royal Family of England, transmitted to them from their ancestors of the House of Brunswick. Two instances of this have been just related, to which may be added the more recent cases of their Majesties George IV. and William IV., who both laboured under heart affections; his late Royal Highness the Duke of York, and some other members of the same family.

The hereditary predisposition to one particular disease is, doubtless, influenced by the intermarriages which have taken place between the different branches of the same family: a practice which, however justifiable on other grounds, is not sustained by the result of medical experience on the influence of such marriages, or the moral and physical character of individuals.

Of the various cavities of the heart, the *ventricles* are most obnoxious to rupture. This we are prepared to expect from the greater effort necessarily exerted by the ventricles in propelling the blood—the one, over the body; the other, through the pulmonary circulation. Although the thinness of the coats of the auricles might induce us to suppose that rupture should frequently occur in them, a reflection of their uses will at once lead to a different opinion: these being nearly limited to propelling the blood through the auriculo-ventricular openings into the respective ventricles. And, indeed, it may be well questioned, whether they are very active in this office, as the power of dilatation, which resides in the muscular parietes of the ventricles, is sufficient to cause the influx of blood into the interior, without any aid from the auricles.

The great density, too, of the muscular fibres of the auricles points out that they can exert but little influence on the blood in filling the ventricles.

How it could be supposed by an intelligent being, that these fibres should produce the active pulsation, or stroke of the heart, felt beneath the nipple of the left breast, is, to say the least of it, most extraordinary; it is only to be regarded as one of the numerous visionary theories so constantly brought forward by the speculative geniuses of the continental schools.

Of the ventricles, the left is most frequently ruptured.

According to the celebrated Corvisart, rupture of the heart rarely occurs, except when this organ has been in a diseased state, "the affections which dispose to rupture being aneurisms, ulcerations, softening of the muscular fibres, and violent contusions of the organ." (b) To these may be added, fatty degeneration and calcareous deposits.

(a) "Morgagni de Causis et Sedibus Morborum," ep. xxviii. 7.

(b) "Dictionnaire des Sciences Medicales," p. 480.

The same authority (a) states, on the subject of the rapidity with which death ensues in cases of inflamed heart, "It is to be supposed that death is always the result of the effusion of blood which follows this accident; I must remark, however, that death, which is sudden in the greater number of cases, does not follow with equal promptitude in others. Many observations prove that it sometimes does not take place till the third or fourth day, because, no doubt, the blood escapes in such cases by a small or an oblique orifice, so that it flows slowly and in small quantity."

"Morgagni (lett. xlv., art. 15) relates a case of an old invalid who was seized with a violent pain, which seemed to ascend from his abdomen to the chest, accompanied with great difficulty of breathing, and convulsions. He died on the third day. On a *post-mortem* examination, three openings were found in the left ventricle."

The left auricle also appears more disposed to rupture than the right. Dr. Francis (b) relates a case of rupture of this auricle.

When rupture of the heart takes place, *sudden death* is almost invariably the result; in some cases immediately, in others, after the lapse of a few moments: the interval between the rupture and the decease of the individual depending on the size and shape of the ruptured opening. I use the words *almost invariably*, as, although there is no well authenticated case on record of a rupture of the heart not being followed by rapid death, I consider it quite possible for many days, or even weeks, to elapse from the date of the rupture to the period of the decease, where the opening is of small size; nay, that a recovery may take place.

This theory is supported by the fact of wounds of the heart not being so universally fatal, as was formerly imagined, being recently established by the celebrated Dupuytren, who relates (c) several cases of this description in which death was postponed for a considerable time, and some where the wound had healed without death ensuing from that cause.

In what manner is death induced in cases of ruptured heart?

It is generally supposed that death is caused in these cases by the sudden loss of blood, first inducing fainting, and subsequently death. But this opinion is not correct, as death must rather be ascribed to an arrest of the heart's action, caused by the pressure of the blood poured out into the bag of the pericardium on this organ.

That such was the cause of death in the case of George the Second, is apparent from the recovery of his senses after his fall, his gradual though rapid death, and lastly from the small quantity of blood found in the pericardium, "nearly sufficient to fill a pint cup."

From the resisting nature of the pericardium, it is impossible that a large quantity of blood should become extravasated into its interior, so as to induce death purely from the loss of so much fluid; much larger quantities are frequently lost without any serious results.

In the case of George the Second, the rupture was the right ventricle, which supplies the lungs and not the sensorium, so that the sudden loss of blood could not have affected this, except indirectly, though the general sympathy which exists between all parts of the body, or by the mode just stated.

The quantity of blood extravasated into the pericardium can rarely exceed the capacity of the cavities of the heart, as this organ when distended fills closely the pericardium, which, from its resisting structure, is incapable of much dilatation under the circumstances. Such was the fact in George the Second's case, the quantity of blood extravasated being "nearly a pint," or almost exactly the full quantity containable by the four cavities of the heart, estimating each of

(c) *Secunda Orationes*.

these to hold four ounces; but which is, I consider, rather more than they contain in the normal state.

How absurd the practice in his case! His medical attendant attempted to bleed him! How completely does his conduct support the observations made in a former paper as to the inutilty and charlatanism of resorting to this practice in all cases of sudden death, so generally had recourse to, in obedience to vulgar prejudice, and justified on the grounds that "if it does no good, it can do no harm."

Rupture of the coronary arteries or veins is followed by similar symptoms and consequences; as the blood necessarily flows into the bag or cavity of the pericardium, life will be prolonged, most probably, until this is so distended as to interfere with and arrest the action of the heart.

As this diminution of the heart's action will have the effect of lessening the quantity of blood flowing from the ruptured vessel, the disease or accident has a tendency to work out a remedy for itself; but the *antagonism*, as it may be called, thus necessary to the production of the reparative processes, is too violent, and engages too important a part of the vital system, to permit of its continuance for a sufficient length of time. Death, therefore, ensues before Nature can make any serious attempt towards recovery.

Rupture of the arteries, especially the larger, is of much more frequent occurrence than that of the heart although death from rupture of the artery and subsequent loss of blood takes place in only a very small proportion of aneurismal cases. This is owing to the conservative powers of Nature, which, by engaging the various tissues in the immediate neighbourhood of the tumour, in the formation of the aneurismal sac, as this progresses to the surface, prevents the death of the individual for a considerable time. It more frequently occurs that the patient is exhausted by his sufferings before the aneurismal tumour is likely to burst, and dies rather from debility than from loss of blood, particularly where the aneurismal tumour forms in one or other of the cavities of the body in the neighbourhood of organs important to life.

Sudden death from loss of blood in such cases is by no means rare; numerous instances are on record of aneurismal tumours bursting into the œsophagus, stomach, intestines, &c., thereby inducing an immediately fatal termination.

Aneurisms of the first portions of the aorta may burst into the pericardium; aneurisms of the remaining portions of the arch and of the thoracic aorta burst into the œsophagus, trachea, bronchial tubes, lungs, cavities of the pleura, &c.; aneurisms of the large abdominal arteries frequently burst into the hollow viscera. In all these cases death is induced by the sudden loss of blood, which may be poured out externally or not, according to circumstances.

Aneurismal tumours formed on the cerebral cavity prove fatal by inducing pressure on the nervous structure, either by means of the tumour itself or in consequence of the bursting of this, and the subsequent effusion of blood.

The quantity of blood effused in such cases rarely exceeds a few ounces, as the escape of a larger quantity is evidently incompatible with the continuance of life—this being necessarily suspended by the undue pressure of this fluid on the sensorium.

In few situations can even so much blood be poured out without causing death. In the lateral ventricles—into the substance or on the surface of the lateral hemispheres—a considerable quantity of blood may be effused without compromising the life of the individual, but in no other situation. A small quantity of blood effused into the cerebellum, the base of the brain about the pons Varolii, or medulla oblongata, proves rapidly, and in most cases immediately, fatal. Effusions from rupture of the basilar artery in the immediate neighbourhood of the pons Varolii are especially fatal, as the effused blood presses directly on the ascending and descending fibres of the cerebral mass, so as to at once cut off the currents of nervous in-

fluence in their course to or from the great cavities of nervous energy. So also in cases of effusion about the medulla oblongata, as some of the principal nerves destined to the support of organic life, and the respiratory function, proceed from this situation, namely, the par vagum and glossopharyngeal, and a little more inferiorly the spinal accessory, the phrenic and inferior external respiratory, all of which become paralysed from the pressure induced by the effused blood in the cerebral or spinal osseous cavities.

In these situations Nature is unable to adopt any of those conservative measures so frequently resorted to elsewhere, in consequence of the absence of cellular father-tissues, so favourable to such processes, and the presence of the resisting bony structures which immediately surround the organs affected. The cerebral mass itself, being but little disposed to the adhesive inflammation, cannot aid in such reparative processes, and is further prevented from doing so by the peculiar nature of its functions, which would cease to continue under the change of structure necessary to establish a cure. In ruptures, therefore, in these situations, death is induced, not by loss of blood, but by the destruction of the functions of one of the great centres of life, namely, the nervous system.

Aneurismal tumours of the extremities rarely prove suddenly fatal, and do not therefore belong to our present subject.

Rupture of any portion of the venous system rarely occurs; instances, however, are on record of rupture of the vena cava, vena azygos, vena portae, and other large veins, inducing sudden cessation of life. A much larger quantity of blood may be lost from the venous than from the arterial system without inducing death.

We shall next consider the causes of sudden death in connection with the nervous system.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of June 7; M. BRONGNIART in the Chair.

INFLUENCE OF ATMOSPHERIC ELECTRICITY ON THE SYSTEM. By M. PALLAS.—M. Pallas, chief physician of the army in Africa, asserts that the greater number of diseases, particularly "neuroses," are due to the influence of diffused electricity, the principal sources of which are thunder-clouds and marshy soils. By their geographical constitution, and their effects upon the human organism, marshes (says M. Pallas) present the closest analogy with the galvanic battery. Their deleterious effects are formidable in exact proportion with the quantity of saline or organic matter contained in the waters; and observation proves that diseases developed by the influence of marshy emanations are at first of a nervous nature; hence one of the methods which will be most efficient in preventing intermittent fever and neurosis must be electrical isolation of chairs, beds, and tables from the soil by glass supporters.

RESPIRATION DURING INSENSIBILITY PRODUCED BY ETHER.—M. Ville and M. Blandin forwarded to the institute the results of their researches on the effects of ethereal inhalations. During complete insensibility, these gentlemen have observed that more carbonic acid is evolved from the lungs than in the natural state.

A NEW METHOD OF DRESSING WOUNDS AFTER OPERATION. By M. BATDENS.—This method consists in the application of a circular band above the wound, which is united by the agency of a long and thick cotton thread fixed in front, and at the back by a pin attached to the circular band. The pressure of the cotton is soft and equal, the intervals, intercepted by the loops, permit an easy escape of suppuration, and, by the continued straining on the circular bandage, the muscular structures are forced downward towards the stump, the concavity of which it thus prevented.

Meeting adjourned at five.

ACADEMY OF MEDICINE.

Meeting of June 8; M. DEGIN in the Chair.

ALBUMINOUS URINE.

M. Bouillaud stated, as a fact hitherto unobserved, that when a blister was placed on a surface which had been cupped a short time before, the urine became albuminous during twenty-four hours.

M. Moreau observed that albuminous urine was met with in very numerous circumstances. It was frequent during pregnancy, and constant in the convulsions which sometimes attend parturition.

M. Roger reminded the academy that the fact noticed by M. Bouillaud had been two years ago pointed out in a memoir on cantharidian cystitis, read to the institute by M. Morel.

M. Martin Solon had very often found accidentally albumen in the urine; but it was only in Bright's kidney that it was intimately combined with the renal secretion.

M. Orfila read the first part of a paper on "Some Points connected with Poisoning by Preparations of Lead, Copper, Arsenic, and Mercury."

In this first part M. Orfila endeavoured to solve the three following problems:—1. Do copper and lead constantly exist in the healthy human body? 2. If they do—is it possible to distinguish the natural or physiological copper and lead from those substances when they have been introduced into the system as toxic agents? 3. Is the presence of lead demonstrated beyond a doubt in the organs of persons affected with saturnine intoxication?

In answer to the first question, M. Orfila remarked that the existence of copper and lead in the healthy organs was admitted by M. Serzeau, by M. Hery, and by M. Devargie, but denied by MM. Flaudin and Danger. Since eight years M. Orfila had instituted researches on this point, and had constantly succeeded in demonstrating the presence of copper in the liver of man. The mode of extraction was very simple: the liver should first be carbonized in a china capsule with the lamp of Berzelius; the charcoal should then be incinerated in closed tubes, receiving a draught of atmospheric air; the ashes, washed in boiling water for the purpose of removing some saline compounds, should then be submitted to the action of boiling diluted nitro-muriatic acid, which would dissolve the physiological copper. The produce of the evaporated fluid might then be readily dissolved in water acidulated with muriatic acid, and a piece of metallic iron would cause immediate deposition of the copper. As to the possibility of distinguishing the natural copper or lead from the same substances introduced into the system as toxic agents, the learned professor stated, that in the latter case the metals might always be extracted readily by the action of boiling water, or of boiling water acidulated with acetic acid—a method which always proved insufficient for the extraction of the copper or lead which enters naturally into the composition of the healthy organs. M. Orfila had examined chemically two livers, and the cerebrum of persons who had died from the results of saturnine intoxication, and had demonstrated the existence of the lead by the method which leads him to the detection of the presence of these metals in the bodies of poisoned persons.

HEREDITARY TRANSMISSION OF INSANITY.

A report by M. Royer Collard was read on a paper of M. Baillarger, entitled "Statistics on Hereditary Insanity." The conclusions which M. Baillarger had come to were the following:—Mental derangement is more easily transmitted from the female than from the male parent; it is more frequent, and is propagated to a greater number of children. The madness of a mother is more to be feared for her daughters than for her sons; madness of a father, on the contrary, is more readily handed down to the sons. Maternal insanity is not transmissible to sons in a greater degree than madness of a father; it is, on the contrary, more to be feared for daughters.

The reporter expressed the approval of these

doctrines by the commission, and moved the thanks of the academy to the author. The report was adopted.

Meeting adjourned at half-past four P.M.

ETHEREAL INHALATION IN CEREBRO-SPINAL MENINGITIS.—At the beginning of the present year an epidemic prevailed amongst the troops of the division of Algiers, and its characters were those of cerebro-spinal meningitis: rigidity of the spinal cord, headache, intense pain in the spinal region, tetanic muscular convulsions, delirium, and coma were observed in all cases, the greater part of which proved fatal. M. Baccaron, physician of the Hospital of Mustapha, had recourse to ethereal inhalations, repeated every hour—and even oftener in severe cases. The first effect of the inhalation was to increase the frequency of circulation and of respiration—but only for a few moments; a marked sedation of both these functions being the ultimate result of this method. In the space of twenty-five days nine men were submitted to this treatment: two died, five recovered completely, one was still in a doubtful state, and the ninth was passing from the acute into the chronic form of the malady.

RESECTION OF DISEASED BONE.—M. Larghi, surgeon of the Hospital of Verceil, founding his practice on the acknowledged functions of the periosteum, deprecates generally the excision of bones as it is at the present day performed, and recommends the preservation of the periosteum for the purpose of reproduction of that part which disease has rendered it necessary to remove. The periosteal envelope of necrosis is generally thickened, and attached by weak adhesions to the affected parts, from which it can readily be separated. In most cases, therefore, it is sufficient, according to Dr. Larghi, to make an incision of the soft parts down to the bone, to open the periosteum, to separate the latter from the bone by passing a piece of tape between them, and then to divide the denuded osseous structure, which will afterwards be replaced by nature. M. Larghi illustrates his views by referring to resection of the ribs. This operation was for the first time performed in 1813, by Cittadini, of Arezzo. That distinguished surgeon operated on four occasions, in three of which the pleura was perforated, and in the fourth frightful hemorrhage occurred, and was arrested only by the application of the actual cautery. These dangers, which M. Larghi attributes to the method employed, are certainly not to be despised, and are most probably the cause of the resection of ribs being so seldom performed. The operative process recommended by M. Larghi consists of simple incision of the skin down to the diseased rib, division of the periosteum, and extraction of the necrosis: the intercostal space is not opened, hence no danger of hemorrhage, and certainly less danger of penetrating into the pleura. Also, and this advantage should not be lost sight of: the muscular attachments to the periosteum are not sacrificed, and the space occupied by the bone preserves its natural shape. The operation, thus modified, appears to us both more simple and less perilous than when performed according to the ancient rules. M. Larghi has applied this method to a case of diseased ribs with the greatest success; in another case the greater part of the os humeri was removed, and the periosteum secreted a new bone; a portion of cubitus and part of the os ilii were also excised, and in the latter case lameness ceased after the operation.—*Gazette Medicale.*

THE NEW MEDICAL BILL IN FRANCE.—The debates in the Chamber of Peers on the new bill fill the columns of medical journals; all seem unanimous in applauding the decision of the House, by which a second class of medical practitioners, viz., *officiers de santé*, licentiates, &c., are abolished. M. Cousin supported the institution of *officiers de santé* with considerable but unsuccessful vigour. On this point the decision of the House is received with unqualified satisfaction by all, except, perhaps, the public executioner at Lyons, who is an *officier de santé*, in extensive practice. This fact speaks volumes

in itself against the institution, and would, no doubt, long since in England have raised an insurrection amongst those squeamish gentlemen who feel offended at the introduction of a pastry-cook into the profession. The principle of the *concours* for the nomination of professors will in all probability be adopted; advertisements of medical consultations, and of peculiar methods of treatment, are the object of a special clause in the bill: they are prohibited under a fine of £8 to £40. When sanctioned by the Chamber of Peers, the bill will have to undergo revision before another legislature, and will in all probability suffer considerable modifications before it comes finally into operation.

D. M'CARTHY, D.M.P.

Nutritive Value of Food.—Dr. Christison remarks that the proportion of digestible principles in each article having been ascertained first, the whole of these may be arranged in two divisions, according as they are derived from vegetable or animal substances. And for the most part the nutritive power of dietaries may be valued by their relative abundance in animal proximate principles; because animal food abounds more than vegetable food in those which are nitrogenous. This method, however, is capable only of limited application to practice, for certain articles of animal food contain no nitrogen, such as fat, butter, and sugar of milk. But when duly limited it may be practically applied with convenience to simple dietaries, such as those of the working classes of this country. The other method, which is theoretically more exact, arranges the whole digestible proximate principles, animal and vegetable indiscriminately, in two divisions, according as they contain nitrogen or not. An account is then taken of the quantity and proportion of all the leading constituents, nitrogenous and carboniferous, but especially the former.

The Importance of Milk as an Article of Diet.—It is common for practical men, says the same author, in enumerating the articles in a dietary, or in estimating the nutriment in the food of the labouring classes, to omit or undervalue the milk consumed by them, and to regard that fluid as little else than mere drink. But this is an error. Milk is really an article of solid food, being coagulated soon after reaching the stomach. As new milk contains on an average thirteen per cent. of digestible solids, and skimmed milk ten per cent., the former actually presents fully one half, and the latter above a third, of the nutriment contained in the lean part of beef and mutton; and of the nutritive solids more than a third in new milk, and above a half in skimmed milk, consisting of nitrogenous aliment. Hence, on scientific principles, milk must be a valuable article of food, especially when the food is composed otherwise of little else than farinaceous substances.

Causes of Scoury.—Almost all observers ascribe this disease to some error in diet. At first it was ascribed solely to salted and ill preserved provisions. Subsequently it was found that other errors are equally effectual. Great importance has been attached by some to the mere want of sufficient fresh vegetables, whatever the food may consist of. Others have seen the disease arise seemingly from a deficiency of salt. Others have traced it to mere scantiness of food. A very liquid diet has been thought another source. A diet too purely animal has been known apparently to act with great intensity. On the contrary, a diet too purely vegetable has been suspected to have had the same tendency. And it is now ascertained, from the history of the epidemic in the prison at Perth, that a diet too purely saccharo-farinaceous tends to engender scurvy; that it requires the aid, however, of some co-operating cause or causes, hitherto unascertained; that other uses, also not yet ascertained, may counteract its tendency; and that the use of milk will counteract it even when co-operating causes concur to develop its morbid influence.

Imperfect Vision from Irregular Refraction,

with Night Blindness, remedied.—Dr. Hamilton, in "The Monthly Journal of Medical Science," relates the case of a coach-painter who had incomplete night-blindness, and in the day symptoms which were referable to some irregular refraction of the dioptric apparatus of the eye. On looking at a clock, if the hands pointed perpendicularly, he could not distinguish the hour, but if horizontally he experienced no difficulty. So with all lines, if horizontal, they were perceived correctly; if perpendicular, they were indistinguishable. From his earliest years the state of his vision has always been the same. A careful examination of the eye detected nothing abnormal. There was no pain in the eye, and no tendency to headache. The right eye was the more defective of the two. The case was seen by Dr. Allen Thompson, who repeatedly endeavoured to ascertain the comparative focal distance of the eyes in a vertical and horizontal direction with the head of a pin, and double hole in a card, and found in the left eye—the holes being horizontal—the image became single on one occasion at six inches, and another at from five and a half to six inches; and when the holes were placed vertically, on one occasion, at eight and a half inches, and on another at nine or nine and a half inches. Upon the right eye it was more difficult to make observations, owing to the degree of myopia: the relation, however, of the horizontal to the vertical focus appeared to be as 5½ to 6½ inches. Mr. John Adie, having had some experience in a somewhat similar case, was requested to try lenses of different foci, and, having by him some from two feet to eight inches in length, tried their effect, and found that they operated beneficially, and the weakest the most so, the cylindrical surface being made to act horizontally, or from side to side. The effect of this lens was to lessen the refractory power of the eye transversely, and probably to equalize the transverse curvature with the perpendicular one. Similar glasses for both eyes were fitted into a pair of spectacles, and the result was most beneficial results, the patient being able to see without impediment, the patient being able to see without impediment, and to follow his avocations with complete comfort and entire satisfaction.

The Contents of Encysted Growths.—These (says Dr. J. Bennett) are various, and give a peculiar character to them. They may be a perfectly colourless fluid, resembling water, or the limpid serum so frequently secreted in the lateral ventricles of the brain. It is structureless, and chemically contains a minute portion of salt, and a certain amount of albumen. The contained fluid may have an amber colour, and resemble the serum formed after the coagulation of the blood. It may be more or less gelatinous, sometimes slightly, and like weak gelatine; at others firm, capable of being cut with a knife, like calf's-foot jelly. Sometimes this matter is structureless, at others it may be seen to contain very delicate filaments, combined with pale oval bodies, the outlines of which become stronger on the addition of acetic acid. This kind is common in the ovary, and is sometimes found in the kidney and other organs. The cyst may be distended with epithelial scales, evidently thrown off from its internal surface, becoming compressed together and partially broken down. Hence, on examination, clusters of such scales may be found mixed with numerous debris, fat granules and globules, sometimes with crystals of cholesterine. The contents are usually of a white or slightly yellow colour, which is sometimes fluid, at others semi-solid. The *molluscum contagiosum* of dermatologists is thus constituted. Another kind consists principally of fat, either amorphous, crystallized, or organized—that is cellular. If amorphous, they resemble honey, constituting the *melicerous* growths of morbid anatomists. Many encysted growths contain hair and teeth. The hair is occasionally inserted into the walls of the cyst, at other times it exists loose, mixed with the fatty or other contents. The teeth belong sometimes to the first and sometimes to the second dentition. Occasionally the cysts con-

tain lymph, softened fibrine, and purulent matter, composed of plastic, pus, and compound granular cells, the result of exudation into their cavities. Sometimes the contents of the cystic growth are formed of a solid exudation which has undergone the sarcomatous transformation, and wholly consists of fusiform cells. This exudation may pass into the cancerous formation. Some cysts contain the peculiar secretion of the organ in which they are found: thus, cysts in the liver are full of bile, and those in the kidney of urine.

Vomiting in Phthisis.—Dr. Seymour affirms that vomiting, occurring almost always after cough in phthisis at an early period, marks a severe and rapid form of it; and at a late period that large collections of matter are locked up in the lungs. Against vomiting in this disease he recommends four grains of the extract of conium, to be taken twice or three times a day, followed by this draught:—Lime-water, one ounce; cinnamon-water, half an ounce; syrup, a drachm.

Ectropion.—Subcutaneous Incision.—A young man was admitted into the Hôpital Dieu, under the care of M. Blandin, with ectropion of the lower eyelid, caused by former abscess and exfoliation of the edge of the orbit. An attempt had been made to remedy the deformity by a blepharo-plastic operation, but had failed. M. Blandin operated a second time, by introducing a tenotomy knife, and dividing freely the adhesions which bound down the eyelid, passing the knife all round between the superficial parts and the periosteum. A small incision in the internal angle of the eyelids was added, to render the eyelid more free. The whole eyelid was then drawn upwards, and fixed in its new position by a compress and strips of adhesive plaster. It was stated that great improvement was obtained by this proceeding, but that afterwards ectropion still existed to a slight extent.

Prosopalgia subsequent to Inflammation and suppuration of the Lining Membrane of the Antrum of Highmore.—Willyk, of Toplitz, relates the case of a patient, when sixty-six years old, attacked, for the first time, with violent pain in the left superciliary arch, and less severely in the corresponding eyeball. The pain lasted for two years, commencing every day at 9 A.M., and ceasing at 2 P.M. Quinine afforded only transient relief. In the spring of 1844 the recurring pain extended to the right side of the face, on which side the alveolar process appeared to be its chief seat, the pain being at this time burning and lancinating. Antiphlogistics, locally applied, mitigated the pain; but now the right nostril became obstructed, and simultaneously there rose unusual lachrymation, increased sensibility to light, and a feeling as if the right superior maxillary bone were about to be torn asunder. A tooth, supposed to be the cause, was extracted, but without relief. At last, however, an offensive smell in the right nostril, a nauseous taste whenever the tongue touched the alveolar pit, and a fluctuating tumour on the hard palate, near the site of the extracted tooth, suggested the suspicion of suppuration in the antrum of Highmore. The diagnosis was rendered certain by the penetration of a probe, through the socket of the tooth, into the antrum. Appropriate injections were employed for several months, with the effect of rendering the fluid discharged from the nose completely odourless, when the pains altogether ceased.

New Instrument for Applying Pressure to the Femoral Artery in Popliteal Aneurism.—Dr. M'Crae, surgeon to the Sydney Infirmary, gives an account in "The Australian Medical Journal" of an apparatus which he has used with success for the cure of aneurism by compression. In all cases treated by compression, great pain and swelling from pressure, and obstructed circulation, had been a principal feature. This determined Dr. M'Crae to have an apparatus so constructed that pressure should be made on the superficial femoral artery alone, and in no degree to compress the limb, or to prevent the circulation being carried on by the profunda and its branches. The apparatus consists of a long straight splint,

Similar to that used for fractures of the thigh, only strongly made of iron instead of wood, covered with leather, and having a joint opposite to the knee, so as to admit of its adaptation to those cases in which that articulation cannot be extended, on account of the size of the aneurismal tumour in the popliteal space. Firmly attached to the splint is a circle of iron, also covered with leather, but having several holes in it so as to admit of a screw, at the extremity of which a flat pad is placed. The ring of iron is very strong, and so large as in no degree to press upon the limb; but, for convenience of application, is made to open by a joint. When pressure has been made on the artery, by means of the screw and pad, the patient is prevented from interfering with these, owing to the screw being secured by a small bolt and padlock. Attached to the apparatus is a strip which secures it round the body, and there is also a perineum bandage similar to that used in cases of fracture of the thigh. After the afflicted limb has been bandaged from the toes up to the knee, the apparatus is prepared and applied exactly as in cases of fracture of the thigh: the roller, pad, &c., being similar, and attached in the same way. The bandaging, however, should not extend higher than the knee; and, in order as much as possible to prevent the splint from moving, it should be firmly secured to the body by a roller, in addition to the strap or girdle. This apparatus has been employed with success by Dr. McCrack, and Dr. Henry Hadley, surgeon, 99th Regiment.

Successful Extirpation of an Ovarian Tumour.—*Birth of two Children subsequently.*—Dr. Woycikowski, of Quingay, was called to deliver Mme. Replunard, forty-five years of age. He was informed that, after some pains, a small quantity of fluid had been discharged, and at the same time there protruded from the genitals a tolerably large fleshy tumour. The menses had ceased for fifteen months, during which time she had experienced all the symptoms which had been present in former pregnancies. On examining the tumour it was found to be the uterus, three times its natural size, and allowing the index finger to pass into the orifice. As it could not be returned easily, the abdomen was examined, and found to be distended with fluid; pressure, however, produced such tenderness that the form of the internal organs could not be ascertained. Paracentesis was immediately performed, and thirty-five litres of yellowish transparent fluid, without odour, were removed. A tumour was now discovered in the abdomen, the size of a man's head, round, modulated, floating in the pelvis above the brim, and quite indolent. The uterus was now replaced without difficulty, and the patient ordered to remain in bed, and have low diet. Ovariectomy was performed the next day in the usual manner, in eight minutes. The tumour removed weighed six pounds and a half. The tissue was lardaceous, yellow, and very resistant, and contained internally several purulent collections. The treatment consisted in low diet, and lemonade for drink. Twenty-five days after the operation the patient was well. In four months after, the woman became pregnant, and at the usual time gave birth to a boy. She was delivered in December, 1846, of a second boy. Both children are living.

Composition of the Blood in Puerperal Fevers.—M. Hersent divides puerperal fever into three kinds: first, the bilious; second, the pure inflammatory; and third, the typhoid. He has studied the blood in three cases of the first class, eight of the second, and four of the third. Of the first class, one was taken ill immediately, and one twenty-four hours after delivery; and the third, at the commencement of the fourth day. Of the second class, there were taken ill after delivery, four, one day; one, thirty-six hours; one, three days; one, four days; and one, five days. Of the third class, one was taken ill during labour; one, fifteen hours; one, eighteen hours; and one twenty-four hours after delivery. The following table will show the ratio between the quantity of fibrine in the blood of a healthy pregnant female at the ninth month, and that of pa-

lients labouring under different forms of puerperal fever:—

	Maximum of fibrine.	Average of fibrine.
In a healthy pregnant female, at ninth month ..	4.8	4.3 Andral and Gavarret.
One case only of the bilious form of fever ..	5.7	4.4 Hersent. *
One case only of the inflammatory ..	6.7	4.1
One case only of the typhoid ..	7.1	4.3

With regard to the quantity of albumen, the average has been ascertained to be, in the normal state, 70; pregnancy, 66; the bilious variety of puerperal fever, 55.1; inflammatory, 35.9; and in typhoid, 42.7. The quantity of water in the blood is in general in the inverse ratio of its solid contents. The average quantity of globules, according to Andral and Gavarret, to be in the healthy pregnant female, 110; according to Becquerel and Rodier, 111.8; bilious puerperal fever, 141.5; inflammatory, 111.0; and in the typhoid, 82.3.

The Forceps in Delivery.—Dr. West, in his "Report on Midwifery," remarks that Dr. Hoffman applied the forceps twenty times in 637 labours, or about one in 30 cases. Dr. Ramsbotham, once in 729 cases. The deaths after application of the forceps in Dr. Hoffman's practice were 35 per cent.; in Dr. Ramsbotham's, 6.12 per cent. Dr. Hoffman on one occasion, having applied the forceps while the head was at the brim of the pelvis, succeeded in extracting the child, but, in so doing, tore asunder all the joints of the pelvis, and lacerated the urethra and vagina, of which injuries the mother died on the eighteenth day. Such is the dangerous force that may be exerted by this instrument.

REVIEWS.

Practical Observations on some of the Diseases of the Stomach and Alimentary Canal. By JAMES ALDERSON, M.D., F.R.S., &c. 8vo. London, 1817; pp. 215.

This work is, simply, as it modestly professes to be, a collection of cases, and of reasonings upon them, which have constituted the valuable opportunity of an active professional lifetime. Amongst the many ailments which it occurred to Dr. Alderson to treat, in his extensive career as physician to the Hull General Infirmary, stomach diseases formed not an insignificant part: his more important cases he faithfully narrated and annotated, and, when requisite, had drawings taken; and these things, in their collected form, compose the volume before us: a volume of which any author might justly be proud, and in whose favour it gives us the greatest pleasure to speak.

Throughout the work, our author treats the different divisions of his difficult subject with a masterly hand: just in the style, in fact, of a man who has seen all that he says, and is satisfied to discourse only from the results of experience well reflected upon. In the pages which compose this volume are many scattered facts and comments, concerning the more serious diseases of the stomach, which will repay attentive perusal. The varieties of carcinoma of the cardiac extremity of the stomach, of the œsophagus, of the pharynx, and of the pylorus, are treated of in a most practical manner. A curious nervous affection of the œsophagus is thus narrated:—

"Mrs. —, aged forty, married, was seen by me in conjunction with Mr. Hurdey. She complained of great pain in attempting to swallow even liquids, and expressed her conviction that her throat was growing up: she had been ill only a fortnight, at the commencement of which time she had inadvertently swallowed an angular peppermint drop. It stuck in the throat, and caused considerable pain, since which time she had been unable to swallow anything; even liquids gave her excessive pain.

"After much persuasion, she allowed a bougie to be carefully passed down the œsophagus, and

from that moment all difficulty in swallowing ceased. Can we suppose, in this case, that the lining membrane of the œsophagus was cut or lacerated by the angular bon-bon, and thus a spasm of the muscular coat of the tube induced, which, until artificially overcome by the introduction of the bougie, the patient had not power to relax? or are we to believe that the difficulty of swallowing was of a purely nervous character altogether, akin to what, for want of a better or more expressive term, is called hysteria?" (Pp. 46, 47.)

The latter we should say, decidedly. If rupture of the lining membrane of the œsophagus had caused the sense of constriction, the passing of a bougie would not have cured it. There are few parts of the body that are more apt to convey false notions of their condition than the œsophagus. Nervous and fanciful people have always got "something sticking in their throats." Hysterical women are thus perpetually being choked with what they have an objection to swallow. We are acquainted with a gentleman, whose gullet, to judge by his eating, is of ordinary capacity, yet he cannot swallow a pill for fear of being choked. Once or twice, in attempting, or rather performing, this feat, he has been kept up half the night with a suspicion that he should be suffocated. So strong was the fear upon him the last pill he swallowed, that he resolved for the future to eat his pills, and he has done so ever since.

The chapter on the comparative symptoms in "structural and functional disease" of the stomach is excellent. Its leading points are thus treated:—

"Pain.—In the early period of structural disease, pain is not in all cases present: the absence of pain, accompanied with other well-known symptoms, leads to the presumption that a disorganizing process is being carried forward insidiously; when pain is present, it is at the pit of the stomach, of a lancinating, grinding kind, and usually confined to a particular spot. In the strictured form, pain is more acute and more defined than in the areolar or colloid.

"The functional disease is peculiarly marked by pain, which is more diffused, and intermits, coming on at intervals according to the stage of digestion. The suffering is never of the acute, lancinating character, and yields in a temporary way to the use of alkalis.

"Fluid vomited.—The dark-coloured fluid, approaching nearly to the character of venous blood, is a peculiar mark to distinguish structural disease from mere functional derangement of the digestive organs. In the latter complaints it is never present.

"Progress and Development of the Disease.—The structural disease comes on so gradually and insidiously, that the patient is often unable to give a history of the very commencement of his illness; and cases have occurred in which a considerable state of disorganization has taken place before the attention of the patient has been directed to his condition by any train of tangible symptoms.

"In functional disease, symptoms of the derangement of the digestive organs force themselves very early on the feelings and attention of the patient, and the magnitude of the suffering seems to exceed the actual amount of disease; and the patient presses his symptoms earnestly, and dwells minutely on the circumstances of his case." (Pp. 196–201.)

Appended to the volume are some coloured plates that well illustrate different forms of stomach disease. The whole reflects great credit on the industry, acuteness, and judgment of the author, and cannot fail to be most acceptable to the profession.

Cold and Consumption; or Consumption—its Prevention and Cure by Cold as a Constitutional, or Inhalation as a Local, Agent; involving the Causes, Symptoms, Medicinal Treatment, &c.; with a Sketch of the Anatomy and Physiology of the Respiratory Organs. By HENRY C. DESMON,

Member of the Royal Colleges of Physicians and Surgeons, London. London: Henry. Henshaw. Exeter: W. Balle. 1847; pp. 153. It is a very great pity that members of the profession, who wish to occupy an exalted place in society, should consider it necessary for the attainment of their object to write a book. A physician is in general considered a learned man; and it would be very wise in many to let the public enjoy that opinion without an attempt to prove it through the medium of the press. Numbers there are who have cut but a sorry figure in the literary world, and we greatly fear that Dr. Deshon will be added to the list. To write well upon any subject, which is considered comparatively easy to handle, requires not only the possession of intellect, but the judicious exercise of the mind; how much more are those required in taking up such a subject as "consumption"—to investigate the causes, describe the symptoms, and point out the mode of treatment to effect a cure! The most illustrious minds have here felt their weakness, and lamented it; while, however, they have done much in this department of pathology, much more remains to be accomplished; and our author has stepped forwards courageously, if not discreetly, to remove all the difficulties.

Dr. Deshon has chosen as a motto for his book two lines from Horace, "*Si quid novisti,*" &c., a passage which has been hacked about by quacks and "silent friends," to teach the public that they are clever scholars as well as famous doctors. Our author could certainly not have been acquainted with this circumstance, or he would have left the aforesaid gentlemen in undisputed possession of this part of the Roman bard. The object of the monograph is stated to be "to detect the reasons of the sad mortality from phthisis; to determine accurately the nature, character, and causes of this disease; and to develop the treatment, preventive and curative, based as conceived upon sounder views of human physiology. It has been long the opinion of the author that a principal cause of failure in the treatment of this disease has resulted from regarding it as necessarily fatal, and consequently that the only resources consisted in the adoption of mere palliative, or placebo treatment." Budleigh Satterton, in Devonshire, must be a very outlandish place for medical literature does not reach it; and we do not wonder that the doctor there should think as he does, and then write as he does, for the benefit of the profession and the public.

The first chapter of the book contains a "Sketch of the Anatomy of the Organs of Respiration," and it is certainly one of the curiosities of medical literature. There we are told "that portion of the body denominated the chest, but in anatomical language the thorax, is situated, most appropriately, at the upper and fore part of the trunk, and is divided from the abdomen by a fleshy muscular septum, situated horizontally, and called the diaphragm, or midriff." The doctor then favours his reader with a pretty little diagram to show the three spaces which exist within the chest, and which he informs us are "term'd, from their locality, media." He then employs the following illustration:—"Place any two round or oval bodies, two bladders filled with air for instance, side by side; if a tape were tied round them, two triangular spaces would be formed. Insinuate any other rounded body, such as an orange, between their approximated sides; call the tape the thoracic parietes; the bladders, the lungs; the orange, the heart; and name the spaces thus formed severally anterior, middle, and posterior mediastinum, and you have not an incorrect idea of a transverse section of the chest." This is capital simile, but he uses one shortly after which beats this hollow. After informing us that the principal vessel of the heart traverses the posterior mediastinum in company with other important parts, he goes on to say, "The sinuses of the bladders may serve to elucidate this: if these oval bodies, still bound together by a broad tape, were so arranged as to have their long axes from

above to below, a space would exist between their sides, through which it would be possible for the vessel in question to pass with facility, and which would then very much resemble a common walking-stick (which I shall now call aorta, from *aorta*, to suspend), being suspended from the heart; the crook itself, or arch of the aorta, winding in its course over the right pulmonary artery and left division of the trachea; while the body of the stick, or thoracic aorta, descends to the left of the vertebra in the posterior mediastinum."

Only imagine the physicians, surgeons, and general practitioners of the United Kingdom sitting with all meekness and humility as pupils at the feet of Dr. Deshon, and learning from him that the chest is near the head, and not the tail—that the heart is a muscular bag—that the aorta resembles a walking stick; a most striking metaphor, certainly—that the pleura line the interior of the ribs and the upper part of the diaphragm, and are reflected over the lungs, bearing the same relation to them as does the head to the old double nightcap! Well done, doctor! the profession after this must neither want instruction nor metaphors. We cannot help supposing our author must have seen some fat, gouty, old gentleman, with nightcap on head and stick in hand, pacing up and down the street of Budleigh Satterton, Devon, which helped him to the sublime metaphors cited above. At page 19 we are informed, "that owing to this affinity (a disposition to mechanical admixture) the atmospheric composition of azote and oxygen is found by weight invariably the same, whether examined on the surface of the broad Atlantic or in the arid plains of Arabia, on the icy shores of Greenland or in the burning climes of the equator!"

We are really surprised that such a book—written, we suppose, for the instruction of the medical profession, and dedicated to G. J. Guthrie, Esq., "for his unceasing efforts to raise the character and tone of medical education"—should have issued from the press in the nineteenth century. We would advise the doctor, for his own credit, to buy up, forthwith, every copy: for in the book there is neither good writing nor valuable information.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carver, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

Caution.—There can be no legal claim; the parties who gave the advice must have done it with an intention to deceive.

A Surgeon.—1. Right appreciation of the signs of complete insensibility is of the utmost importance, unless these signs are carefully observed, it will be impossible to ascertain the right moment for the commencement of an operation; a patient might thus endure a great amount of pain, when a few more respirations would have freed him from suffering. 2. *Stearns's Inhaler*.

C. E. L., Luton.—If the request were granted it would confer no benefit, and therefore the offer must be declined.

A Lover of Science.—By applying to the secretary of the college, personally or by letter, an admission ticket will be obtained.

Sigma.—The "University Calendar" will give the required information. The degree is certainly a respectable one.

Mr. Wheatstone.—Mr. Churchill is the publisher, and the price is moderate.

M. D., Maidstone.—Injections of a solution of nitrate of silver have been found extremely useful. It is worth a trial in the case mentioned.

A Candidate.—1 The diploma of a German uni-

versity confers no privileges in England, and, obtained simply for money, is only a proof of individual vanity and corporate avarice. 2. No.

Invalid.—The custom is as dangerous as it is ridiculous, and it has not even novelty to recommend it. Consult a respectable practitioner.

Mr. E. Smith.—The communication has been received, and is now under consideration.

Medicus, Sheffield.—It is not within our province to undertake the inquiry suggested.

A Bartholomew Student.—Interesting cases should have a place in the note-book. A good knowledge of anatomy is indispensable.

An Obstetrician.—The treatment must be determined by the stage and severity of the affection. An examination is necessary, though the patient strongly objects, as it is the only means of ascertaining whether ulceration has taken place.

Rusticus.—The letter had better be addressed to Dr. Streeten, who perhaps may give our correspondent the required information. The parties to whom reference is made have petitioned against the Registration Bill. The committee was certainly a secret one.

An Injured General Practitioner.—There is no redress. It is a successful evasion of the Apothecaries' Act, and the evil would be greatly increased under the Registration Act. Patience and watchfulness are necessary.

F. C., Glasgow.—The fee cannot be recovered. The testimonials will entitle the possessor to become a candidate for the diploma of the London College of Physicians.

An Assistant.—1. The reward is not in proportion to the labour. 2. The Medical School affords good instruction at a moderate price.

An Old Subscriber, Brixham, Devon.—We have for some time declined opening our pages for the controversy. Neither party intends to be converted, and the medical world is not sufficiently interested in the matter.

Mr. James.—It rests with the Lord Chancellor, who also fixes the scale of fees.

Dr. Channing is thanked for his communication.

A Surgeon-Apothecary will find the information he requires in the last week's number of the Pharmaceutical Times. The Conspectus of the Five Pharmacopœias is still in course of publication.

An Old Friend.—If the case is not a fabrication, our correspondent will at once furnish us with his name and address. Internal evidence is not in its favour as a truthful statement.

An Admirer of the National Institute.—Very few have withdrawn, though the most strenuous efforts have been employed to shake the confidence of the members.

An Admirer of Truth.—The publication has altogether changed its character, and is in a hopeless condition.

Mr. W. Edgar.—The communication is an advertisement.

A Member of the College of Surgeons, England.—The society will not exercise its authority in the matter. The greater part of the profession has unhesitatingly declared that the certificate of the company is more respectable than the diploma of the College.

Mr. J. W. Roll, Cupar, Fife.—Question 1. We think not. 2. If a graduate of the university. The fees are very low. 3. From the foreign booksellers in London.

Mr. P. C. Richardson, Hartlepool.—It is likely the Company will not prosecute, though they have the power. The five years' apprenticeship cannot be dispensed with. It is likely the rules of the society says who is to certify; if not, any medical certificate will do.

Chirurgus, Kilkee.—No.

A Subscriber.—The evidence before the select committee will be soon brought to light.

N. G.—Noad's Lectures.

U. S.—The entire quantity of blood in the system is supposed to pass through in that time. To the second question see answer, No.

Mr. J. B. Abercromby, Kensal New Town.—The letter shall appear next week.

O. P. has been received.

A Practitioner with Two Tails.—Under consideration.

Mr. Davis.—We make a rule not to recommend any assurance company; but our correspondent cannot fail to make a good selection after a careful perusal of our advertising columns.

Achates has handled the subject of the parliamentary committee, and the equivocal obscurity with which it is enshrouded, with a severity well merited, but at too great a length for our pages.

Ward should send up his petition at once. Remarks of H. D. on a contemporary are inadmissible.

A Constant Reader.—The respectable publisher named will send a catalogue if our correspondent state his reasons for requiring one.

An Admirer is thanked for his good opinion, but we never prescribe.

P. H. suggests that a copy of the "Secret Companion," bound in calf, should be sent to every member of "the quack committee," inclusively of the medical M.P. for Finsbury.

An Old Bird, deceived on the single occasion of his crediting a contemporary, should write, without drawing his name.

Mr. F. B. H. labours under a mistake. The work is deficient—as far as our knowledge extends.

Dr. Poupert's second paper on the Materia Medica in our next.

The complaint of B. (Manchester) about the abandoned lectures of Liebig, Lane, Schoubein, Müller, Liston, Baillarger, &c., is not sent to our notice.

Several correspondents have requested us to send out the numbers of the Medical Times stitched. There is one sufficient reply to these requests, that from the extent of our circulation we should be unable to comply with them without a delay of days.

Letters and communications have also been received from Dr. Shirley Palmer, Birmingham; Mr. Forsley, Sarill-rou, Cantuar; A Subscriber; Chirurgus, Kitzee; Mr. W. Edgar, Mr. P. C. Richardson, Northwood; Mr. J. W. Ball, Cupar, Fife; A Member of the College of Surgeons, England; An Admirer of the National Institute; An Admirer of the National Institute; A Surgeon-Apothecary; Dr. Channing; Mr. James; An Old Subscriber, Brizhan, Doron; An Assistant; F. C., Glasgow; A Surgeon; C. E. L., Luton; A Lover of Science; Mr. Wheatstone; R. N., Middlesbrough; Sigma; A Candidate, Mr. E. Smith; Modicus, Sheffield; A Student of St. Bartholomew's Hospital; Obstetrician; Rubens; An Injured General Practitioner; Dr. J. C. Cox, Naples; O. Mr. J. B. Abercromby, Kensal New Town; A Practitioner with Two Tails; Mr. Davis; Mr. A. Markwick; A General Practitioner; An Old Friend.

THE MEDICAL TIMES.

SATURDAY, JUNE 19, 1847.

THE REGISTRATION BILL AND THE CHEMISTS AND DRUGGISTS.

We are quite content that the value of the "Shabby Bill"—this thing of shreds and patches barbaically pilfered from the abused project of Sir James Graham—shall be tested by its vaunted tendency to suppress all medical practice, save of qualified persons.

1. It neither directly nor indirectly touches the Holloways, the Gosses, the Curtises, or any other of the mischief-making and mutilating "professors," "herbalists," or "surgical consultants," who infest the metropolis and our other large towns. They are left as they were before—as free chartered as the wind to blow deception and death on whosoever wealth and ignorance can offer as a victim.

2. Beyond such empiries, the great cry of the medical profession has been directed against the increased and increasing encroachments of the body of CHEMISTS AND DRUGGISTS. Does the bill suppress this evil? No. Does it tend to diminish it? No. Will it increase it? *Faustly.*

This is our emphatic proposition: the Registration Bill leaves the field of medical practice wholly open to the chemists and druggists. We proceed to place this truth beyond the admission of a doubt.

By clause 9 every legal restriction, whether imposed by statute or charter, on illegitimate practice, is repealed. Here are the words:—

"Be it, therefore, enacted, that so much of any act or charter granted before the passing of this act, as prohibits any person from practising medicine, physic, or surgery, in any place, without such license as is mentioned in any such act or charter respectively, or that imposes any restriction or penalty on the practice of medicine, physic, or surgery, further than is contained in this act, shall be, and the same is hereby, repealed."

With regard, then, to the chemists and druggists, as indeed in regard even to the worst kind of empirics, we are left, for all our defence and protection, to this single, untried, untried measure. We are condemned to abandon, for this untested and crude novelty, all those bulwarks—of whatever kind we may have against quackery—which have withstood the ordeal of the law; and some of which, in recent days at least, have proved of such active and exemplary efficiency. Now, what is the amount of the new provision for our safety? Here is the clause (the fourteenth):—

"And be it further enacted, that if any person shall, after the 1st day of January, 1848, act or practise as a physician, surgeon, or apothecary, in any part of Great Britain and Ireland, without being duly registered according to the provisions of this act, and without having a certificate as aforesaid in force at the time of his so practising or acting as a physician, surgeon, or apothecary, he shall, on conviction before any magistrate having jurisdiction in the county, city, or place where the offence was committed, forfeit and pay a sum not exceeding £5, nor less than 10s., for every such offence, to be recoverable within three months next after the commission of the said offence, as is hereinafter described."

Now, we might make at least twenty objections to this *sole means of repressing quackery* the new bill would leave us. It is untested, and there are few untested provisions through which an acute-lawyer would not drive his "coach and six." It is certainly not more effective, in any sense, than the "Society's" recently-developed procedure of indicting the offender for misdemeanour. Then there is no party like the Apothecaries' Society to assume the inviolable task of informing, or to bear the trouble and expense of prosecuting. Again, the clause is so vague and indefinite, there remains so much obscurity as to the fact, or series of facts, that will constitute an acting as physician, surgeon, or apothecary, and the words would lead to such absurd consequences, if rigidly interpreted, that there are at least ninety chances in the hundred that prohibition could not be enforced. But, if all these considerations are strong in reference to quackery of all kinds, they gain an immensity of force when we add to them this plain fact, that

THE BILL WHOLLY EXEMPTS THE CHEMISTS AND DRUGGISTS FROM THIS VERY PROHIBITORY CLAUSE.

We subjoin clause 28:—

"Provided always, and be it enacted, that nothing in this act contained shall extend, or be construed to extend, to prejudice or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing, and vending drugs, medicines, and medicine compounds, wholesale or retail; but all persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise, and carry on the same trade or business in such manner and as fully and amply, to all intents and purposes, as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this act."

We shall not amplify on the words here given, further than to say that they in so many words "legalize" the present "use, exercise, and carrying on of the chemist and druggist"—whatever may be the kind or character of such present "use, exercise, and carrying on." The bill repeals all former restrictions in respect to the chemists and druggists; it repeals also its own restrictions, and this in favour of the chemists and druggists; and then finally it gives the chemists and druggists the legal right to carry on their business and practice just in the same way as they may have happened to have carried it on in this year, 1847!

But it may be said that the bill restricts them from practising medicine, at least as physicians, surgeons, or apothecaries. It does no such thing, but exactly the contrary. It would have done it, perhaps, if there had been no exception made in favour of the druggists and chemists—but, to show clearly that the bill has no intention to stop any such practice in them, a clause is inserted specially for their exception.

The bill, of course, without any such exception, never intended to stop their practice as chemists and druggists: it only dealt with a perfectly different thing—the practice of apothecaries, surgeons, and physicians: but because it did deal with the latter practice, prohibiting it to the unqualified, and therefore to the chemist and druggist, it became necessary to introduce a new exceptional clause, which now distinctly exempts the chemists and druggists from the penal provisions of the measure. If they now, as chemists and druggists, act as apothecaries and surgeons, so may they after the passing of this measure: the only difference will be, that if this bill pass they will so act in complete and glorious impunity.

But then the falsehood is protruded, that this clause is only a repetition of the clause in the Bill of 1815. The answer is easy. The Apothecaries' Bill had reference not more to the practice of physic than the sale of drugs, and it was obviously right to reserve to grocers and druggists that power of selling drugs which they previously possessed and exercised. But the trading habits of the chemists and druggists before 1815 were not precisely the same as those existing through the years before 1847, and, while the judges have decided that before the Act of 1815 the druggists possessed not the usage of playing the part of apothecaries or surgeons, it is very certain that the judges can make no such decision in reference to the present day; especially when they have before them an act regulating medical practice alone, and yet distinctly exempting the chemists from the only restriction it imposes—the only restriction, indeed! it will leave for us on unqualified and empirical pretenders.

That this is the legal effect of the proposed bill, we have no more doubt than of our own existence; and, were a dubitation left in the

minds of the judges having to decide on the subject, it must inevitably produce, *in favorem libertatis*, a judgment favourable to the druggist, and his now legalized pretensions.

We might well look on this legalization of druggist-practice with alarm; but we are far from certain that, if the bill pass, we should have here its whole pharmaceutical mischief. Often has it been propounded that the chemists and druggists should have a partial medical education, with certain subordinate diplomas: the physicians, or some of them, are fond of the scheme: the *Gazette*, before its decease, more than once announced the project as desirable: with Ministers and poor-law guardians there would not be wanting to it some recommendation: let us then connect with this judicial recognition of the druggists the 23rd clause in the same bill, which gives the Secretary of State the absolute power of fixing the *curricula*, fees, and examinations that are to precede letters testimonial, "according to the nature thereof"! and which testimonials may therefore be nearly as cheaply got in England for the "apothecary" as they are, or have been, in Ireland—nay, far lower, if such be the Minister's predilection! We would earnestly advise the general practitioners to attend to the varying diplomas which, "according to the nature thereof," are to be had as cheaply or dearly for the future as it may suit the convenience of the Home Secretary to fix!

Is there a settled design in all this? Is there a subtle attempt in the wounded castaway to exact a severe retribution on those general practitioners who have repudiated all connection with him as worse than calamitous? We will not say; but our suspicions are certainly not quieted by finding the drowsy organ of the Pharmaceutical Society yawning out its satisfaction in terms like these:—"We have heard no one expressing objection to the principle of medical registration." "The objections are ably answered by the author of the bill." "We hope some mutual concessions will be made for the purpose of effecting, if possible, an arrangement satisfactory to all parties"! What a quiet way has this Mr. Jacob Bell of expressing his raptures!

MEDICAL REFORM IN FRANCE.

For some time past the medical profession in England has been agitated to its very centre upon the subject of reform, and, while there has been but one feeling in reference to its necessity, there has been a great diversity of opinion as to the best means to be employed in order that it may be accomplished. This has arisen from the constitution of the profession itself, the members being arranged in different classes according to the system of education adopted to render a candidate eligible for examination at one or other of the chartered medical institutions. The result has been that one section of the medical profession has looked with jealousy on another, and attempts have been made to establish the interests of a few to the irreparable injury of the welfare of the greatest numbers. Self-elected corporations have endeavoured to perpetuate their abuses—universities, venerable on account of their age, but possessed of slender means to impart an efficient medical education, to retain their privileges—and ambitious men to accomplish their designs amid the perplexity which has resulted from the present order of things. Medical reform has, therefore, to the present moment been postponed, and there is not that effective organiza-

tion in the profession which is necessary for its members to obtain a permanent and advantageous settlement of the question.

While, however, we have been so much occupied with our own differences, as to prevent a legislative enactment in our favour, Medical Reform has been making rapid progress in France, and there is a fair prospect of its being speedily brought to a satisfactory conclusion. Last November, 5000 delegates from all the medical practitioners of the kingdom met in Paris. In the Hôtel de Ville they held their sittings for fifteen days, and the Minister of Public Instruction, having heard their suggestions, consented to bring in a bill which should effectually annihilate everything which was calculated to injure the honour and usefulness of the profession.

This body in France is composed of two orders—doctors of medicine, and *officiers de santé*: the former are graduates of one of the three universities—Paris, Montpellier, or Strasburgh, the latter are an inferior grade, merely received by medical juries. A certain number, also, of foreign graduates are practising in France by virtue of royal ordinances. All candidates for the degree of M.D. must have graduated as bachelors of letters and sciences in the Sorbonne of Paris, or the faculties of Strasburgh or Montpellier. The period of their studies is four years, and they have to undergo five examinations; of these two are practical, the candidate being required to dissect in the presence of the examiners, and to inspect scientifically two patients selected in the hospitals. The thesis is in French or Latin, and the examinations are public.

The *officiers de santé* are examined by three persons, called a *jury médical*, which sits in Paris, and visits the departments twice a year. This order of medical men are not allowed to use the title of "doctor," though they do that of "*médecin*," an appellation common to each; and they are permitted to practise only in the department in which they have been examined. The present penalty for illegal practice is fine or imprisonment.

The principal points of reform in the new bill relate—1. To the two classes of medical practitioners. The *officiers de santé* are to be suppressed, this having been demanded by a great majority in the Congress. 2. To the suppression of illegal practice, an offender being liable for the first offence to imprisonment for not less than six months, or more than two years; for the second offence, not less than two years, or more than five. 3. To foreign physicians who desire to practise in France. By the new law it is proposed that no foreign medical man shall be allowed to exercise his profession in France, unless it shall have been previously decided by the Royal Council of Public Instruction that his diploma or degree is equivalent, as an attestation of length of studies, and respectability of the university which conferred it, to that granted by the French faculties. The authorization may be restricted to a certain locality, or confined to a limited period, and is revocable at pleasure.

The authorities who have the superintendence of medical education are twenty-four in number, and are appointed by *concours*, the Minister having the privilege of appointing the first professor to a newly-created chair. The judges of the *concours* are chosen partly from the professors of the faculty, partly from the Academy of Medicine; and the election is subject to the approval of the King. At present all M.D.'s have a right to contend for a vacant professorship; but the new law proposes to exclude all

but *agreges* from this privilege. The professor's salary is 10,000 francs, while that of the *agregé* is only 2000 francs. In several provincial towns secondary schools are established, each of which has its professors, whose certificates are recognised by the faculties. The new law provides for the formation of laboratories in the faculties; and secondary schools, where the student will be forced, by frequent *post-mortem* examinations, to acquire a knowledge of the organic lesions accompanying the various diseases to which the human frame is liable. The foundation of *bourses*, or gratuitous exhibitions, to be enjoyed by *laureats* of the universities and secondary schools, is in contemplation. It is proposed, still further, to establish a class of medical men, under the denomination of *Médecins Cantonaux*, who must have graduated as M.D.'s, and who are to afford gratuitous attendance on the poor, in consideration of a fixed salary. It is supposed that the *Conseils de Médecine* will devote their exertions almost exclusively to the compilation of statistical documents and to public *hygiène*.

We have thought it our duty thus to give a brief outline of those changes which are about to take place in the medical profession in France, in order that our readers may contrast them with Mr. Thomas Wakley's panacea for all the evils which afflict the medical community in our own country. The one is demanded with united heart and voice, and is tolerably adapted to accomplish the most beneficial results; the other is a mere piece of patchwork which nineteenth-century surgeons of England repudiate, because it gives but few benefits that it may hide numerous evils. We admit that it has been lauded by some as a gift which the profession ought to receive with many thanks. Amongst the number, however, but few English general practitioners are to be found, though the most unscrupulous means have been used to urge them to become parties to their own degradation.

Reform in this country, it is true, is beset with many difficulties, from the number of chartered bodies which possess the authority of granting licenses to practise; this is not the case with our Gallic neighbours: there the university is the *alma mater* of the profession, and, after a sound education, grants a degree to the candidate which is respected throughout the civilized world. France will allow of no half-instructed practitioners, and she has resolved that the *officiers de santé* shall be speedily suppressed. Pride has not prompted her to this, but a supreme regard for the interests of medical science; and, influenced by the same illustrious motive, she is about to establish gratuitous exhibitions, that intellect may not be excluded from the profession because an individual may have no gold to pay for its cultivation. The example thus set cannot be entirely lost upon the nations of Europe; let it teach us to advocate such a change as shall abolish unjust distinctions, foster rising intellect, and make the medical profession in Great Britain universally renowned for its learning and liberality.

MOVEMENTS IN THE PROVINCES.

We have received information of active movements in the provinces against the Medical Registration Bill. Petitions, numerous and signed, are in progress in Nottinghamshire, Yorkshire, Lincolnshire, Bedfordshire, Lancashire, Surrey, and various other counties. We congratulate the profession on this renewal of activity in a cause where the interests of science are as much

concerned as the individual welfare of the members. It is highly desirable that public reprobation should be strongly expressed against this measure—the very worst that was ever foisted upon the attention of the profession. Our exertions to defend its meditated evil must not flag. If good men were as zealous in a good cause as bad men are in an evil one, we should have no fear about the utter discomfiture of this wicked attempt. We must be up and stirring.

Individuals should forward petitions to the representatives of their boroughs and counties, for immediate presentation to Parliament. Two or three sentences, in condemnation of the bill, are sufficient for the purpose. We are sorry that we have not space to publish the numerous letters and copies of petitions that we have received, commenting for the most part in terms of great indignation on this mischievous bill. This is a fine healthy spirit, which should be energetically exercised, so that it might be made *practically useful* to the cause. Let each gentleman, convinced of the great danger of this measure, induce his neighbour to *petition against it*. This is the way to make public feeling *tell* upon the special committee.

IRISH APOTHECARIES AND ENGLISH CHEMISTS.

TO THE GENERAL PRACTITIONERS OF MEDICINE, &c.

GENTLEMEN,—The efforts of the Editor of a certain obsolete medical journal to counteract the legitimate influence of my addresses to you are so extravagantly inconsistent and whimsical, that it requires more asceticism than I am possessed of to resist the cachinnatory impulses which such melodramatic exhibitions are accustomed to excite. A fortnight since I was traduced and vilified by the same individual, who last week, strange to relate, condescended to become my humble imitator. The writer whom Thomas Wakley professed to despise, he now honours with the most slavish adulation.

Whatever may be my merits or my demerits, I may be permitted to inform Mr. Wakley, that, however closely he may affect my manner and sentiments, there will still be a chasm between us over which his small faculties will never carry him. We are birds of a different feather. My merits are not his, and, thank God! his vices are not mine. He may continue his mimicry, blow my trumpet, dress himself in my garments, and imitate my gait, but the most unpractised eye will, despite all his arts, be able to distinguish between the man and the monkey.

A single specimen, gentlemen, extracted from the article in question, will exemplify the justice of this condemnation. The writer, ambitious of a heroic flight, commences a paragraph with a ludicrous imitation of St. Paul, thus:—“*Men and brethren, are not these things so?*” “*Men and brethren!*” Faugh! It is clear that Thomas Wakley has mistaken his mission: he should have been a preacher in a conventicle, or the tragic hero of a band of strolling players; the part of *Pistol* or of *Macbeth* would eminently suit his genius. This tender mode of entreaty irresistibly reminds us of the black slave's appeal to his white master—“*Am I not a man and a brother?*” However, adopting the phraseology of the champions of the *Tournament*, which he revives with amusing grandiloquence, he goes on to say:—“*Pick up the glove of opposition which is lying on the ground, and bring your unfelt strength into this bloodless contest.*” And for what

glorious purpose do you imagine, gentle reader, that the heroes of medical agitation are exhorted to buckle on their armour? The next words inform us:—“*Turn the tables on the foe, as undoubtedly you can; and then the words will read—We at last the conquerors, they at last the conquered!*” So, all this hard fighting is to end in putting your foe under the table! This imagery reeks strongly of the Freemasons' Tavern. There is but one step from the sublime to the ridiculous. Mr. Wakley has taken it, and no one will envy him the success of his enterprise. Imagine the successful combatant shouting in triumph over the body of his enemy lying prostrate under the table! Alas! Thomas Wakley, this is sad drivel; *Leary's* madness is rationality in comparison. Perhaps, after all, it is a mere joke, since the writer has taken care to inform us that he means no harm, for he distinctly avers that he wishes it to be a *bloodless contest*—a fight with the gloves on—a mere mimicry of greatness—a scenic farce got up for the amusement of the public. The article should have been headed—*KILLING NO MURDER!*

Such trash as this can never be imposed on the profession as fine writing; or as common sense. This is a part of the puppyism of literature—of that desire to be brilliant and distinguished in the display of qualities with which we are not naturally endowed. Stays and a shirt may make a fop, but they cannot make a gentleman. The arguments are as false and hollow as the style is stilted and absurd. Neither is worth further notice.

There are two other points, gentlemen, embraced in the Medical Registration Bill, to which I am desirous of directing your attention. I have already condemned so many clauses of the measure, that you may be scarcely able to imagine the possibility of another point of assault. A little further consideration, however, will unfold other evils inherent in the scheme, and demonstrate the utter worthlessness, or worse—the great peril of its various provisions. It is amazing to see how so small a measure can be stuffed so full of injustice.

By the clause it is provided that any individual in Great Britain or Ireland, who possesses a license to practise as an apothecary, shall be enabled to register; and, by virtue of such registration, it is subsequently provided that such individual shall be empowered to practise medicine in all its branches, in all parts of her Majesty's dominions.

The point that I now desire to urge upon you is the position of the Irish apothecary in reference to this bill. The licentiate of the Apothecaries' Society of Ireland is, at present, the chemist and druggist of that country; and, although trenching upon the duties of the surgeon, and gradually shouldering him out from general practice, he is not recognised as a regular general practitioner. He is, in fact, an interloper, and practises on the mere civil right of the English chemist and druggist to do as he pleases. For many years these practitioners underwent no kind of examination, but were merely, what the great majority of them are now, mere traders in drugs and groceries. Latterly the governing body of the society, finding that their members were creeping surreptitiously into practice, have required a course of study and examination in the sciences pertaining chiefly to their own particular business: for example, pharmacy, chemistry, botany, &c., as the Council of the Pharmaceutical Society in London exact now from their members. The Irish apothecaries

gradually increased in number, and practised more extensively as medical men: the council of the society, somewhat ashamed, perhaps, of the presumption of their members, still were not unwilling to make good the ground that they had invaded, and, in the year 1841, added a year's course of study in medicine to their *curriculum*, and thus accomplished their members to a certain extent to act as medical practitioners. A veil, at all events, was thrown over the impropriety of the acts of the members. It was no more just than if the council of the Pharmaceutical Society should examine in medicine, and declare their members qualified to practise medicine.

Still, gentlemen, I must confess that I am not in a situation to judge whether, in reference to the social condition of Ireland, it is desirable that these infringers of the rights and duties of Irish surgeons should be admitted under a new law, as the qualified medical practitioners of that country. It is, to this extent, a matter of expediency, and must be settled by the Irish authorities themselves. It cannot, however, be overlooked that these gentlemen are comparatively ignorant of medicine: for, even by their most extended curriculum, not more than *one third* of the medical knowledge required from the Irish surgeon is required from the Irish apothecary.

Whatever, then, may be the expediency or the wrong of this clause of the bill as respects Ireland, there can be no doubt, gentlemen, that it would affect most injuriously the English practitioner, inasmuch as it would permit some thousands of uneducated men, tempted by the opportunities which London and the large towns of England present for making money, to practise medicine in this country. The gross iniquity of this proceeding is obvious, and I apprehend that the whole profession, both in England and Ireland, will resent the attempt to perpetrate so foul an injustice.

Yet, gentlemen, Mr. Wakley endeavoured *silently* to push a bill containing such a clause through the House of Commons, and medical men have been found sensible enough to give it their support! This clause of the bill is so important to the interests of the profession that an inquiry into its justice or necessity was imperatively demanded before an attempt was made to constitute it a law. Can the profession consider themselves safe in the hands of such an unscrupulous person?

The other point, gentlemen, for your consideration is the probable result of an entire abolition of apprenticeships as a portion of the educational course. No man can deny that shameful abuses have corrupted the present system, which is now turned to the profit of the master rather than to the advantage of the student. The end of this institution is to instruct the young man in the preliminary knowledge and duties of his profession, and not to constitute him merely the drudge of his master. Yet the master generally conceives that he has a just moral claim upon the entire services of his pupil; is affronted at neglect, and not unfrequently exacts duties which neither good taste nor gentlemanly feeling can approve. He forgets his own obligations as a teacher, and remembers only the obligations of his pupil as a servant. This has been, and is, the great evil of the system—an evil which has corroded and undermined it, and made it repulsive to every man of enlarged views and fervid zeal for the honour of his profession.

The system of apprenticeships is a part also

of our connection with *trade*, and in this respect degrading to our professional character; the very name is offensive, and, with some other titles, should be cast off as the remnants, the crust, and the *reminis* of the past.

I am not, however, gentlemen, an advocate for the *entire abolition* of the system. The period of *five years* is undoubtedly too long; but a shorter period of *two years*, or at the most *three*, would, I apprehend, be useful to the student, and acceptable to parents and teachers. Restraint during the first years of adolescence, when the pulse beats riotously, and the passions yearn for gratification, is absolutely necessary to the formation of sound moral habits, and to the preparation of the mind for submission to a severer discipline. It would be highly improper, as a general practice, to send a young man forth from his father's roof and at once to launch him, inexperienced in the arts of the world, and unprepared by habits of self-reliance, into the giddy vortex, the tumultuous agitation, and treacherous currents of metropolitan life.

Setting aside, however, these moral considerations which are obvious to all, and which I have no time to dwell upon, it is not probable that the majority of young men would spend two or three years of their life in acquiring a knowledge of the *material medica*, pharmacy, and dispensing, &c., unless there were some imperative regulations in operation to that end. If a knowledge of this branch of professional art is necessary for the general practitioner, as I maintain that it is, then it cannot be properly acquired under two or three years, and certificates showing that the pupil has spent this period in the acquisition of such knowledge should be *required by law*.

Consider, gentlemen, what would be the *immediate* result of such a sweeping abolition of apprenticeships as this bill proposes. Any *chemist and druggist* would be enabled in two years, nay, in *one year*, as in the case of the pastrycook Blake, to obtain the diploma of the Royal College of Surgeons, and act as a legal practitioner of medicine! The profession would be overrun by a bastard breed of general practitioners got by the Council of the Royal College of Surgeons out of the body of the chemists and druggists! The chemist and druggist, who now illegally plucks the bread from your hand, will, in about a year or two, be enabled to legitimize the robbery, and snap his fingers in your face. He, as well as yourself, will be able to exhibit his diploma, and laugh at your vexation and your ruin.

It is the vaunted *friend* of the profession, gentlemen, that has prepared so admirable a scheme for your degradation: it is the self-styled man of liberal views, of generous desires for your welfare, of elevated patriotism, of pure and earnest love of his profession; of experience, knowledge, sagacity, forethought, incessant activity, and splendid promise: the man who has denounced all other schemes as infamous, frustrated the self-denying exertions of other labourers in the same cause, and stigmatized their conduct as deceitful and atrocious; the man who is at once the conscience, the oracle, the prophet of the profession:—no less a man than he has devised a scheme which, of all others, would, if a law, be most destructive to your interests and subversive of your professional character—a scheme which is as faulty in conception as it would be injurious in operation; which is as pitiful in design and end, as the pretensions of the author are huge, hollow, and ridiculous.

Gentlemen, a great career is opening for the general practitioners of medicine in this country—a new era has arrived, new powers are in activity, immortal achievements are already foreseen, and prophetically animate us to their accomplishment. The future is pregnant with our labours. Her rewards, her honours, her medallions, and olive crowns are *ours*: let us persevere and hasten to possess them. There are fine, ardent, struggling potentialities in the general practitioners that require only freedom from corporate bondage, and a fair field to attempt the highest, to accomplish the greatest, labours that ever have or that ever will adorn or dignify our profession. We must not only *have* knowledge, but also the liberty to use it, and the opportunity to cultivate it. Not only the *tree* of knowledge, but the *fruits* also must be ours. Science must be a courage among us, and its objects promoted by us. Knowledge has rights, and not the least of these is self-government in all its comprehensive liberty, to act, teach, adjudicate, and reward. Knowledge demands independence, and she will have it; her claims may be for a time disregarded, but they must be heard and conceded: she "is power."

Do we not know and feel these things? Then let us set about accomplishing them. I know but of one mode: an institution in which the general practitioners can regulate their own affairs, foster the emulous love of knowledge that now distinguishes them, and establish their independence and their respectability on a broad and honourable basis. To this end we must come.

I have the honour to be, Gentlemen,

Yours, very faithfully,

VOX VERITATIS.

LETTERS TO THE MEDICAL PROFESSION OF THE UNITED KINGDOM.

LETTER III.

GENTLEMEN,—On Tuesday, the 1st of June, I had the melancholy pleasure of being present at a meeting of the friends of "The General Medical Annuity Fund," held at the George Hotel, Northampton. Unfortunately, the greater part of the business of the day had been transacted ere I reached my destination; I, however, arrived quite in time to hear my own project or provision for the superannuated and disabled members, and the widows and orphans, of our neglected profession denounced as visionary and utopian; to see it torn piecemeal, and scattered to the winds of heaven.

Yet had I happily been gifted with the fluency of speech, and the fervid eloquence, which distinguish the Secretary of the Newport Institution, I might, peradventure, have succeeded in unfolding this project of my brain in fairer proportions than it obviously exhibited to the eyes of the *fourteen* assembled gentlemen, imparted to it a less startling and extravagant character, and, with a calm and deeply cherished confidence in its ultimate achievement which neither the arguments of the mere arithmetician nor the trigid calculations of the actuary can weaken or extinguish, fearlessly confronted it with its more favoured and finished rival. This, however, is not the first time a good and noble cause has suffered damage from a sorry advocate. I was, in fact, too ill and, in some respects, too much taken by surprise, either to speak boldly in defence of my own project, or need an address in explanation of the necessary details, which had been expressly written for the occasion. Like the prudent General, I retreated from untenable ground to occupy a position in which I may, at least, hope to sustain a less unequal conflict.

My second "Letter to the Medical Profes-

sion" was written under circumstances of peculiar disadvantage; my energies depressed by illness; my mind distracted by many and deep anxieties. I had calculated that there would be a large gathering of the profession at Northampton, and naturally felt anxious that such an opportunity of introducing my project to such an assemblage should not pass unimproved. I had, consequently, little time allowed for the composition of my letter, and was denied the ordinary privilege of revision previously to its publication. All these circumstances were most expertly, I will not say unfairly, turned against me by the advocates of the Newport plan.

To imagine, for instance, that I should propose to commence the distribution of pecuniary aid to the unfortunate of our profession, on the liberal scale which I have specified, before a fund, amply sufficient to justify such distribution and to ensure its continuance, had been accumulated, were to question the soundness of my judgment, the integrity of my reasoning faculties. Had I proceeded to explain views on the means of accumulating such a fund, I should have requested the gentlemen present to recollect divers passages in my first letter, of which no copy was at hand, and the few who had read it seemed to remember little or nothing. I should have called to mind the anticipated contributions or bequests from the opulent and childless of our own profession, and the soul-offerings of the wealthy and benevolent of other classes, in testimony of their respect for the high character and bearing which we sustain in the social system, for our unwearied and frequently gratuitous devotion to the cause of suffering humanity; or of gratitude for the inestimable services conferred upon themselves, or their families, in the trying hour of pain or peril. "These, gentlemen," I should have observed, "are the sources upon which we must principally rely. The great bulk of the profession will do little for itself; we can no more depend upon it than on the 'rope of sand,' to which my lamented friend the late Dr. James Johnson, a few weeks before his death, most aptly compared it." And how strikingly might this argument have been illustrated by adversion to the fact that, of some three dozens of medical gentlemen practising at Northampton, four only had honoured us with their presence on that day!

Lampooned and ridiculed though he be by the thoughtless and the vulgar in their heyday of health and vigour, and, on all occasions, shamelessly spurned and neglected by the rulers of his country, (a) yet is there no human being looked up to, in the dark season of individual or national calamity or danger, with deeper

(a) In my way to Northampton on Tuesday, the 1st instant, I read, in the *Morning Herald* of that day, a statement which, if it be true, reflects the deepest disgrace upon the Viceroyal Government of Ireland, and will call down upon it the scorn and execration of every just and generous mind. In a communication from the Dublin correspondent of that journal, it was there distinctly stated that, while the house-painters and carpenters were regularly receiving five-and-sixpence, the stipend of the medical officers of the fever hospitals, in Ireland, had, by an express Government order, been reduced to the paltry allowance of *five shillings a day*; and that, in consequence of the perils from infection to which these courageous men are incessantly exposed, it is utterly impossible for them to effect an insurance on their lives. However this be, should the paragraph in question, or these indignant comments on it, chance to meet the eye of Lord John Russell, or any gentleman interested in the honour and stability of his lordship's Government, I do hope that a searching inquiry will be immediately set on foot; that the crying wrong, if it have really been perpetrated, will be forthwith remedied; and that ample justice will be rendered to the outraged feelings, and the claims, of our zealous and devoted brethren in the fever hospital of Ireland.

anxiety, respect, and confidence, than the humane and accomplished professor of our noble art. The powerful influence and control which, by the exercise of his talents and his virtues, the conscientious and enlightened practitioner may acquire over the minds of those around him, and the beneficent account to which this moral ascendancy may be most honourably converted, it is superfluous to explain. Twice, in the course of my professional life, have valuable estates been tendered, inopportunately tendered, to my acceptance by grateful and confiding patients. From feelings which those most intimately acquainted with my character will best appreciate, the generous offer was, on both occasions, pertinaciously rejected. But had I, when those offers were made to me, contemplated the formation of a Medical Benevolent Fund, what course should I have felt myself justified in pursuing? Most unquestionably, I should have qualified my lofty rejection of the splendid boon by a supplication in behalf of my less fortunate professional brethren. "Bequeath your possessions," I should have said, "to those who are better entitled than myself to enjoy them; but leave, at your death, fifteen hundred or two thousand pounds to my Benevolent Institution; and the prayer of the widow and the fatherless shall daily ascend, in your behalf to the throne of mercy; and the blessing of the destitute shall be with you in your dying hour." At the auspicious close of severe or perilous illness, the human heart, when overflowing with gratitude to God and man, for mercies unexpectedly vouchsafed, and attentions successfully conferred, may, also, be often appealed to, in the sacred cause of misfortune, with resistless eloquence and admirable effect. These, gentlemen, I repeat are the springs of bounty, these the sources of supply, upon which we must mainly depend for the full and triumphant achievement of our great project.

There is one principle in the human mind to the existence and operation of which I may, in concluding the present letter, very properly advert: mankind invariably exhibits a willingness, and even an anxiety, most powerfully to assist those who most strenuously and successfully exert their energies to ameliorate their own condition; and succour those who have been the most earnest and fortunate in the effort to help themselves. Small attempts, however laudable, as they promise no great or striking results, are too commonly despised and neglected. On this principle, alone, I regard the *Timeworth* project: it was first conceived, twenty years ago, in the ancient capital of the Mercian kings, as preferable to, and ultimately more certain of success than, its Newport rival.

Be it not, however, for one moment, imagined that I underrate the value and importance of Mr. Daniell's most useful and benevolent plan, or am insensible to the eloquence, the talent, and the labour which have been displayed in, and expended upon, its development. It is a plan which alike reflects honour on the moral and intellectual character and attainments of its estimable projector. And, should my exertions in the cause of the distressed be productive of no other result, it will afford me some consolation, under the disappointment, to reflect that they have at least procured me the enviable privilege of introduction to the little band of enlightened and philanthropic men by whom I found Mr. Daniell surrounded at the Northampton meeting.

In my next "letter" I shall definitively mark out the somewhat modified course which I have decided on, at present, pursuing; and conclude with the most powerful appeal which my head and hand are capable of inditing, to your pride, your honour, and beneficence—to the deepest and the holiest sympathies of our common nature.

I am, gentlemen, truly and devotedly yours,

SHIRLEY PALMER.

Birmingham, June 10.

MEDICAL REFORM.

[To the Editor of the Medical Times.]

DEAR SIR,—The state of anxiety and uncertainty by which the medical mind of England is at present agitated must naturally affect, more or less, every individual connected with that profession, whether at home or abroad.

Allow me, then, to solicit of your kindness space for a few observations relative to Medical Reform, which have principally arisen from the perusal of Mr. Wakley's highly objectionable measure.

Of all subjects that come within the sphere of legislation I verily believe that not one pregnant with more difficulties, beset by more embarrassments, or cursed by more confusion, can present itself to the mind. How many interests to be reconciled, prejudices to be overcome, and established customs to be modified or uprooted; and I may add, what apprehensions to be cast aside, when we contemplate the defeat of every one, whether within the profession or without, who had the courage to approach this monster of administration—Medical Reform! Sangrado's description of the state of medicine to Gil Blas is peculiarly applicable at the present day:—"Ya todo no es mas que un caos en que uno se toma la libertad de hacer lo que se le antoja, y traspasa los límites del orden y de la sabiduría que nuestros primitivos maestros enseñaron."

Mr. Carmichael, of Dublin, attempted reform. His principles were simple and comprehensive. He for years concentrated all the faculties of his powerful mind upon the subject, backed his exertions liberally by his purse, and was sustained by a host of active reformers. Yet he effected nothing. The Apothecaries' Hall of Dublin took fright, and grasped closer the balance of life and death, and, instead of making a united effort against common abuses, professors in the College of Surgeons thundered against the apothecaries, even in detail; the angry fire was returned by the Hall, by members of the same College engaged there as teachers. Mutual animosities were thus excited, a civil war declared, and the sound philosophical views of Mr. Carmichael were completely thwarted.

Everybody knows what an abortion Sir James Graham's reform bill proved. The profession and the public were simultaneously aroused in hostility against it. Then the French Congress in Paris awakened a new spirit of medical agitation in England, and the National Institute sprang up, and, with a zeal and ability worthy of so mighty an undertaking, endeavoured to collect together the scattered fragments of the profession for the purpose of constructing a general organization. In the midst of the proceedings of the Institute, Mr. Wakley brings forward his reform bill, or rather system of registration, differing very little from Sir James Graham's, and equally certain of a *faux succès*.

There is the same scope given to quackery in both, for, provided that anybody do not assume the title of a medical practitioner, he is permitted unrestrained to trifle with the lives of her Majesty's subjects, and to poach upon the province of medicine. Any amateur who pleases may take up medicine for his amusement as he would music or painting. There are thousands of female quacks, and, provided they do not filch by pretend to be medical practitioners, they may dose *ad libitum*. This measure affords neither security to the public, nor protection to the profession. A registration is already kept in all the institutions, which renders a general one quite unnecessary. It is no more required than another general registration of deaths, marriages, and baptisms of the United Kingdom. The article of inspection and supervision of examinations simply says that the Secretary of State may deputize a person to be present at them. In the next, examiners may take candidates to hospital or workhouses for practical examination. Here plainly practical examinations are left to the discretion of the Secretary of State, and examining bodies who possess already the same discretionary power. They may conduct their exami-

nations practically or otherwise as they please. Now, this is treating in a vague and indecisive manner a point of vital importance to public safety and the interests of the profession. Practical examinations are the best, the only efficient, check against idleness on the part of students; and, if carried into active operation, would completely shield society from the horde of incompetent individuals daily let loose upon the world. Why is not a practical examination made imperative, a *sine qua non*, as in France? If the student had to pass a practical examination, it would impose upon him the necessity of attending regularly the hospitals and dissecting-room, and he would not dare present himself, were the examination also public as here, unless well prepared. I contend that a theoretical examination is no proof of that knowledge required for the responsible duties of a medical practitioner, and that granting a license to practise upon such grounds is legalizing murder. A student of the present day, however stupid or idle he may be, is taught to go through his examination as a bear is taught to dance, or a parrot to speak. The replies of a candidate are as mechanically arranged before as the wires of a puppet; and it does not matter in what institution the performance takes place, it is no less a farce, no less a disgraceful mockery of the most solemn of all human laws—*salus populi*. Thus the most complicated parts of anatomy are described, though never seen in the human subject, and the physical and symptomatic characters of disease as faithfully delineated as if pronounced by the lips of Hippocrates or Galen. May we not as reasonably expect a man to be able to make or repair a watch because he could describe the different parts of its structure. I know a practitioner who some time ago took out a surgical degree, though he did not once cut the human integuments during the whole period of his studentship. He succeeded by grinding alone, and, writing to me immediately after, said, "I'm passed." God bless the mark!

Mr. Wakley's bill says, "The qualifications to be uniform, according to the nature thereof." This does not imply that great desideratum, a standard system of medical education. "According to the nature thereof" signifies uniformity only in the different departments of medicine: thus sealing those distinctions which have nowadays no practical existence, and calculated to serve no other purpose but that of causing division amongst members of the same profession and injury to the whole community; for, just as a nation is protected by a combination of physical numbers, that Science which presides over, and is identified with the happiness of, the millions, becomes enlarged and increases the sphere of its utility by a union of intellectual labours. I regret that such a distinction which daily experience disproves is sustained by the College of Surgeons. There are few surgeons whose practice is not almost entirely medical, particularly in the country. Pure surgical cases are the exceptions to general practice, and even in the army and navy in time of peace the rule holds good. Yet the examination of the College of Surgeons is purely theoretical surgery and anatomy. There is no subject on the table, as in France, to test the candidate's real knowledge of either; and upon medical practice he is not asked a question, upon which he ought to be examined in hospital. Yet that very department upon which he is not taken to task at all will constitute more than three-fourths of his practice during his life. Another most essential topic is not touched by Mr. Wakley's bill. It is embraced by Mr. Carmichael's plan of reform—the establishment of a well-defined Institution of Pharmacy, which I must own would be difficult to reconcile with the interests and views of the apothecaries of England and Ireland. This is a problem, yet how can that second state be disregarded? Second, for we are obliged to consider physic and surgery as one. We investigate disease, not from idle curiosity, but in order to relieve our fellow-man; and, if the means of relief be not cultivated *pari passu* with

the progress made in discovering the nature of the numberless maladies by which mankind is afflicted, we labour in vain, and that noble sentiment which draws us near the bed of suffering will in many cases be disappointed. Pharmacy and the practice of the healing art are sister sciences, still possessing an independent existence; and, whilst it is the duty of the latter to investigate the causes, that of the former becomes the not less useful and honourable part of supplying the instruments of relief. Now, is the science of pharmacy (which necessarily embraces chemistry) sufficiently comprehensive and important to require a distinct institution? I will answer by saying, that such is the opinion of the profession and the public in France; and be it borne in mind, that in scientific philosophical analysis, no country is superior to France. The science of pharmacy is scrupulously separated, on the Continent, from the practice of medicine and surgery. So far back as the reign of Louis XIII. an edict of 1638 would punish an apothecary for giving medicine without the ordonnance of a legal practitioner. Even in the reign of Terror—when the wild excesses of anarchy threw the whole social system into confusion, and when town and country became infected by charlatans, in consequence of the decree of the 18th of August, 1792, which suppressed the universities—the College of Pharmacy in Paris was the only scientific society which escaped the ravages of the time, and maintained its position.

I feel, dear Sir, that I have already trespassed upon your valuable space too much, and beg to conclude for the present, confident, from all I know of your enlightened and powerful journal, that you will allow the subject of medical policy to be frankly and freely discussed in all its bearings.

I have the honour to remain, dear Sir, your obedient subscriber,

S. S. MORIARTY.

Dieppe, 132, Grande Rue, May 6.

DR. RYOTT AND "THE MEDICAL DIRECTORY."

THE charges in the letter we inserted last week, in reference to Dr. Ryott, are, we are happy to announce, wholly without foundation. We published the letter, because its statements were made on the avowed responsibility of three medical men; and we the less regret the publication, although, no doubt, temporarily painful to Dr. Ryott, inasmuch as it has enabled him to set himself right in the good opinion of his professional brethren, and has relieved them from suspicions which must have been anything but agreeable. We have ourselves seen Dr. Ryott's diploma as Fellow of the College of Physicians of Edinburgh.—ED.

[To the Editor of the Medical Times.]

SIR, Immediately upon the perusal of the communication which appears in the current number of your journal, we deemed it our duty to address the following letters to your correspondents and to Dr. Ryott:—

TO J. HORNBER, THOMAS HAYMES, AND JOHN HUTTON, ESQs., &c. &c.

46, Princes-street, Soho, June 12.

GENTLEMEN,—We have read your communication to the Editor of the *Medical Times* in the current number of that journal.

We beg to reply that Mr. Churchill is the publisher only of "The London and Provincial Medical Directory," and cannot justly be held responsible for its contents or editorial management; that we published Dr. Ryott's qualification upon the same authority as we published yours, namely, the information he, or it may be some trickster, forwarded to us in reply to our circular of inquiry, a portion of which reply we enclose, in order that you may be able to identify the handwriting.

It is quite possible to register us in regard to the Edinburgh University, for unlike the London licensing bodies, there is no published list of its members, and we have consequently no means of reference, unless it be to the registrar of that university himself. We beg to assure you, it has not been from any want of courtesy or appreciation of the point in question, affecting as it does the interests of the Directory, that we have hitherto omitted to reply to your letters. Every moment of our time has been employed in an important section of our next year's Directory, and on its completion you would have heard from us.

We are, Gentlemen, your obedient servants,
THE EDITORS
of "The London and Provincial Medical Directory."

P.S.—Your earliest possible reply in respect to the handwriting will be esteemed a favour.

TO WM. HALL RYOTT, ESQ., M.D., &c.

46, Princes-street, Soho, June 12.

SIR,—We have received three several letters from medical practitioners at Thirsk, desiring to know upon whose and what authority we have inserted your name in our Directory as a qualified medical practitioner.

For reasons of our own we have not as yet replied to those communications, and this week, in the *Medical Times*, our publisher, Mr. Churchill, has been attacked upon the subject. It will now be necessary to reply, and it will give us great pleasure to be able to show that the information you gave us was correct, and that it is not "an error."

Your reply, by return of post, will much oblige, Sir, your very obedient servants,
THE EDITORS.

To the former of these letters we have received no reply, but from Dr. Ryott we have been favoured with a polite and temperate communication, enclosing diploma and official letters, proving that he is in every respect that which he has represented himself to be—a graduate of a university after residence and examination, and a fellow of the Royal College of Physicians of Edinburgh—facts upon which we ourselves had never the slightest doubt.

From another source we have the satisfaction of finding that Dr. Ryott is not only duly qualified, but highly esteemed in his locality, and in considerable practice—too successful, as it would appear, to be agreeable to his competitors; to this, we fear, may be traced the unworthy animus which has been exhibited against him.

Error in the entry there undoubtedly is, but it is *ours* and not *his*. In the first attempt to compile the provincial portion of our Directory, it would have been strange indeed if errors, clerical and typographical, had not occasionally occurred; but, for the honour of the profession he it said, only in one instance have we been made aware of a wilful misrepresentation of facts such as has been most unjustly imputed to Dr. Ryott. Bold, indeed, must that man be who would deceive us, for ultimate exposure is inevitable.

After this plain statement of facts, we hope to see a suitable *amende* made to Dr. Ryott by his calumniators. As to the imputations they have thought proper to cast upon ourselves, we now leave it to your readers to judge whose conduct is most open to suspicion?

We are, Sir, your obedient servants,
THE EDITORS
of "The London and Provincial Medical Directory."

[To the Editor of the Medical Times.]

SIR,—A letter has appeared in the *Medical Times* of Saturday last which I beg to notice.

I am not a graduate of the University of Edinburgh, nor have ever stated myself to be so, nor designated myself otherwise than the terms of my diploma warrant.

After fulfilling the whole of the conditions re-

quired by the Royal College of Physicians of Edinburgh, and passing the usual examinations, (a) I had the honour of being unanimously elected a fellow of that body in May, 1843. On reference, my name will be found in the published list of the fellows of the college.

I am, Sir, your most obliged servant,

WILLIAM HALL RYOTT, M.D.,
and Fellow of the Royal College of Physicians, Edinburgh.

Thirsk, June 14.

CORONERS AND MEDICAL WITNESSES.

[To the Editor of the Medical Times.]

SIR,—Permit me, through the medium of your popular periodical, to call the attention of numerous readers to what I believe may be called abuses of the Coroner's Court, with a view of rectifying them, and also for informing the medical world of the powers vested in the coroner, especially in reference to the treatment of the medical profession by some of those functionaries.

To elucidate my position I will suppose a case (by no means rare, and which has occurred to myself more than once). A person is found in the agonies of death: Mr. A., a surgeon, is sent for; he promptly attends; tries all his endeavours to save life, but the person dies; his opinion, gathered from symptoms present during life, is, that death was occasioned by poison. After the lapse of a few days he hears that a coroner's inquest has been held on the body; no medical evidence has been procured, yet a verdict of "Died from poison" is recorded. A rather summary but not very proper way, in my opinion, of deciding the cause of death.

Another way in which such cases have been disposed of is the following, in which the medical practitioner is treated with the greatest contempt.

Intelligence of the death of an individual having reached the ears of the coroner, he issues his warrant for holding an inquest upon the body of the deceased person. The surgeon, Mr. A., who saw and attended the case, is summoned to attend such inquest at a time and place named; he obeys the command; and, to his surprise, finds Mr. B. (a surgeon also) there, who has received an order to make a *post-mortem* examination of the body, entirely without the knowledge of Mr. A.—neither the coroner nor Mr. B. having courtesy sufficient to inform him (Mr. A.) of such proceeding.

In this case the evidence of Mr. B. is taken first, or attempted to be taken: if it be so taken, the evidence of Mr. A. can, at the option of the coroner, be frequently dispensed with (which has been done); and Mr. A. has had the privilege of quietly wasting an hour or two of his valuable time, whilst Mr. B. has had the advantage of astounding the jury by his learned observations on the anatomical appearances presented, or of demonstrating the chemical effects of every-day tests and reagents upon the poison he removed from the stomach of the deceased.

Now, I would ask, should these things be? I conceive that no one can by possibility be so likely to tell whether the poison has been administered by the hand of a murderer, or by the deceased himself, as the practitioner who first saw and attended the case. I cannot suppose that the mere fact of demonstrating the presence of a poison in the stomach can at all show how it got there. Under such circumstances then, Sir, has not the Mr. A. a positive right to be examined, and cannot he demand such an act of justice from the hands of the coroner? If he does not possess this right, the subpoenaing him to such a tribunal is made the vehicle of an outrageous insult to him personally, and highly derogatory to the profession, of which he may be a retiring member.

[The coroner acts unfaithfully to his office in both the cases given: in one of them he also acts illegally.—Ed.]

IS THE SOCIETY OF APOTHECARIES IN EXISTENCE?

[To the Editor of the Medical Times.]

SIR,—I have addressed, within the last twelve months, nearly a dozen letters to the Society of Apothecaries, relative to the prosecution of a person named John Frost, practising without a qualification. Hucknall Torkard, in this county, without receiving the slightest notice of their receipt. To me the prosecution of this man is of the utmost importance. I have collected evidence, and forwarded it to the society, which would indubitably lead to conviction, undertaking at my own cost to prosecute, if they will furnish me with such instructions, derived from their past experience, as will put me into a train most conducive to a favourable result.

In the letters sent by me from time to time I have stated the residence of the parties, attended and prescribed for their diseases, and have forwarded bills and receipts given, according to the printed instructions furnished me nine months after my first application to them. Is no notice to be taken of, no prosecution to be commenced against, a man who has got into practice without one day's attendance upon lectures, one single fleshing of a scalpel, one ingress into a hospital porch? Is he to hold the appointments of surgeon to clubs, which he does in my district, and send the public to their long homes, in blind confidence, without a sixpence having been expended on his education, without the necessary test being applied to him as well as ourselves? Whence do we derive advantage from dangerous and long-continued study, if the society will not notice such flagrant cases as this, one of the most gross, unjustifiable infringements of the privileges we are supposed to obtain from the possession of, and payment for, the Apothecaries' license? I wish no expense to be incurred by the society: their pockets are too shallow, their willingness to fight the battle of their licentiates too weak, to undertake all the numerous actions they should enter into; but courtesy, common decent courtesy, should claim from them at least a reply when they are applied to. I am not singular in the slight thrown upon me: others equally ready to fight this fight in the criminal courts have met the same contempt, the same studied, careless indifference to our oft-repeated addresses on this subject. Why have the society issued manifestoes stating their willingness to prosecute, and withheld even the small gratification we should derive by a communication directing the best means to be employed against individual instances of illegal practice? Am I or others to see year by year roll by, and our means of subsistence taken out of our mouths by such supine indifference as the very men who hold the power of prosecuting, but fail to use it, show? Let them rather positively state that their license is of no value to the owner, then uphold a position before the world detrimental to the adoption of future legislative measures, because Parliament believes in the existence of a check to illegal practice where it exists not, and consequently a work of supererogation to invent new laws. A sword unsheathed is no terror to the riotous; a code unenforced checks not the illegal mountebank. But I am infringing upon your valuable space by this digression; and I therefore, living a long distance from London, conclude by asking whether the Apothecaries' Hall—where I had to register at for three long years, where I paid my money for a diploma after testing my capability to practise—still exists? whether there are clerks and officers at that dingy worn-out home of the apothecary? whether, in fact, there

who close enough to the practitioner whose bread depends upon the effectual trespassing under foot all such disreputable mountebanks.

I remain, Sir, your obedient servant,

ASAPH KNOWORTH.

Surgeon to the Basford Union and

Bulwell District.

Bulwell, near Nottingham, June 14.

SIR JAMES EYRE ON OXIDE OF SILVER.

[To the Editor of the Medical Times.]

SIR,—It is right that we should be well informed respecting all the properties of the oxide of silver—a comparatively new medicine, which is gradually, but surely, becoming universally received by the profession.

If your correspondent, Mr. Underwood, had read my "Practical Remarks," published two years ago, he would have seen that, in the fifty or sixty cases there concisely stated, I invariably administered the remedy in combination with the compound powder of iataganth—a powerless vehicle, from which no evil effects could possibly arise.

Two years of additional experience, gained in private practice and at a public charitable institution, enables me to state that the only drawbacks I have heard of have arisen from its employment in cases in which it has been directly contraindicated—namely, during the existence of febrile symptoms, and when the oxide was not properly prepared.

The first objection I have fully anticipated elsewhere; and the next is too obvious to require a moment's consideration.

As to its alleged effect of blackening the skin, I have not met with it in one single instance, during the interval of five years, since its introduction to public notice; and the two recorded cases (which rest upon isolated testimony) appear to have been produced by a species of unwarrantable perseverance in its employment. I can safely aver, if for the rest of my life I were debarred from using more than a dozen remedies, I would place high in the restricted list the oxide of silver.

If medical practitioners will only accept reasonable testimony, and will apply this valuable remedy, judiciously, in cases adapted to its use, and in the manner I have fully indicated, I can unhesitatingly assure them that their expectations will in few instances be uncrowned by success.

I am, Sir, your very obedient servant,

JAMES EYRE.

Lower Brook-street, Grosvenor-square, June 15.

DEATH OF MR. WALKER, SURGEON, MANCHESTER.

[To the Editor of the Medical Times.]

SIR,—

"What shadows we are, and what shadow we pursue!" said the celebrated Burke. So it is with men and things, when viewed dissociated from the hopes of Christianity and immortality, of which, with the Roman orator, we must say,—"Si in hoc erro, lubenter erro, nec mihi hunc errorem, quo delector, dum vivo, extorquetur volo."

Our friend Walker, surgeon to the Eye Hospital of this town, died on Tuesday, the 1st inst., in the prime of life, at the age of forty-four years. It is supposed that he had taken the fever, of which he died, on the tenth day from its accession, whilst prosecuting his duties as a surgeon to the Manchester union. By his death, society has lost a most amiable and unassuming character, the profession a bright ornament, ophthalmic surgery a clever and rising practitioner, and his family a kind and affectionate husband and father. Unfortunately, like many of our profession, he put off till too late the insurance of his life for the benefit of his family. His widow and numerous family are left, I believe, without any provision. The board of guardians have

intimated their wish to meet the family to some extent, and a committee formed, presided over by the mayor for the same purpose.

The late Mr. Walker was known by his writings, particularly by his "Oculist's Vade Mecum," far beyond the precincts of this town and, if any benevolent professional friend wish to contribute his mite, it will be gladly received and acknowledged, if sent to Elkannah Arncliffe, Esq., mayor of Manchester; or to Mr. Windsor, Piccadilly, Manchester, senior surgeon to the Eye Hospital; or to Mr. Noble, surgeon, Piccadilly, Manchester: or to myself.

Your humble servant,

A. W. CLOSE.

Grosvenor-street, Manchester, June 14.

COPY OF A PETITION FROM REIGATE, SURREY.

TO THE HONOURABLE THE COMMONS OF THE UNITED KINGDOM OF GREAT BRITAIN AND IRELAND IN PARLIAMENT ASSEMBLED:

The humble Petition of the undersigned Medical Practitioners at Reigate in Surrey

Showeth—

That your petitioners have attentively read a bill now before your Honourable House, entitled "A Bill for the Registration of Qualified Medical Practitioners, and for amending the Law relating to the Practice of Medicine in Great Britain and Ireland."

That while your petitioners most anxiously desire an improved regulation of the medical profession, and in particular a registration of all authorized medical practitioners, they are of opinion that the present bill is objectionable in many points, especially in the clauses which relate to the education of future medical practitioners.

That your petitioners believe that no system of medical polity can be useful to the public and to the medical profession which does not place the education of future general practitioners under the direction of their own class, whose interest as well as duty it will be to maintain a high standard of education.

That the bill now before your Honourable House fails in this most important point, and, being altogether subversive of the present state of medical legislation, will not substitute an improved system, but the contrary.

Your petitioners, therefore, humbly pray that your Honourable House will not pass the bill into a law in its present form.

John Steele.

Peter Martin.

George Hampton.

Thomas Martin.

Joseph Sargent.

COPY OF PETITION FROM EAST RETFORD.

TO THE HONOURABLE THE COMMONS OF GREAT BRITAIN AND IRELAND IN PARLIAMENT ASSEMBLED,

The Petition of the undersigned legally-qualified General Practitioners

Humbly sheweth—

That your petitioners consider "The Medical Registration Bill," now before your Honourable House, calculated to retard that advancement in the education of medical men, and in the sciences of physic, surgery, and midwifery, which the public require; and

That they beg the aforesaid bill may not be enacted into a law.

And your petitioners will ever pray, &c.

SUGGESTIONS

FOR A MORE SIMPLE ARRANGEMENT OF THE

MATERIA MEDICA,

BASED ON ITS PHARMACEUTICAL AND THERAPEUTICAL RELATIONS.

By GEORGE LEITH ROUPELL, M.D.

Cantab., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Bartholomew's Hospital, Lecturer on Materia Medica at the College of St. Bartholomew's Hospital.

PREFACE.

In my last paper I endeavoured to show that some further classification of the materia medica was desirable, the numerous subjects included under that head tending to create embarrassment and confusion. The efficacy of our drugs has now been ascertained, in almost all instances, to be due to certain principles capable of separation in an isolated state and in a pure form. These, when carefully prepared, are found to constitute but a small portion of the whole substance formerly employed and exhibited as medicine. It has always been one great object of pharmacy to discover improved methods of thus preparing our remedial agents, and greater convenience of form has been constantly aimed at by all medical practitioners. This has been achieved by the pharmacutists of the present day, and to them great credit is due for the vast improvement which has taken place in their especial department of science. We are now furnished with remedies, not only powerful in effect, but of finite in composition, a more accurate method of analysis, joined to an enlarged acquaintance with the constituents of organized bodies, enabling the pharmaceutical chemist to accomplish with certainty this object. Modern pharmacy, it was remarked, consists to a great extent in the preparation of these principles, and the use of them in practice is rapidly superseding the employment of what we may almost term the crude and raw material. Proximate principles, then, that combination of elements derived from, and eliminated by, the various kingdoms of organic nature by which morbid actions are controlled, obviously demand our chief consideration in studying this division of the materia medica. An accurate knowledge of their properties is essential in the highest degree to the medical practitioner; it is essential as enabling him to detect impurity and adulteration; it is essential in order that he should exhibit them efficiently and securely, it is essential with the view of investigating the operation of our remedies, and of endeavouring to detect their hidden mode of action. The study of the natural orders of plants shows us, in the vegetable world, how directly structure and function are allied, furnishes us with abundant instances of whole families accurately resembling each other, as well in their products or results of their vital actions as in their outward shape and character. These facts are in the highest degree curious and interesting; they are, moreover, important; for although we could

not in medicine substitute one for another, relying upon the mere relationship, yet the knowledge we thus obtain multiplies largely the sources from which the principles alluded to may be derived. What I am endeavouring, however, to inculcate is, that it behoves us to regard our drugs pharmaceutically and as remedial agents, not botanically, and it was stated as my opinion that we should best advance the study of materia medica by condensing the matter which it embraces, and by simplifying the form in which it is usually presented to the student. The best plan of doing this appears to me that of classifying drugs according to the leading characteristics, chemically speaking, of the active agent which they may contain. It has long been my desire to accomplish this task, and even now it may be thought premature to attempt it, the composition of some substances being still doubtful or unknown. To wait, however, till all questions of the possible constituents of organic bodies were ultimately settled would be to postpone indefinitely this improvement in arrangement, if improvement it be. Not in other sciences is such completeness thought essential. The enumeration of the law of gravity was made long before its full bearing could be perceived; application tested its soundness, and errors in its use were corrected by experience. The advocates of the natural system of plants are agreed only in the general outlines of the various families, groups, and alliances of plants. Though of one mind with respect to the leading features of their orders, the minutest subdivisions are sufficiently diversified. Whole classes in the animal kingdom are removed from one sub-regnum to another as improved knowledge discovers more or less perfection in their structure, and points out more strictly their rank in the scale of creation. To delay, then, my proposed arrangement because analysis in certain instances would be defective, or because the active ingredient in some drugs had not yet been decided upon, would be an unnecessary scrupulousness. Nor is it incumbent upon us to consider any classification as complete or final: it is enough if it can be shown that by it information can be more readily conveyed to the mind of the student, and more easily retained in his memory. We may, indeed, create in imagination a perfect arrangement, but that must imply a thorough understanding of the functions of the human frame—of nutrition, growth, and decay—with the full insight into all that takes place in the blood for

the regeneration of the tissues and the purification of the circulating fluid. When we know all this, and can estimate the influence of all disturbing causes, from whichever of the innumerable sources of disorder they may be produced, we may then look forward to some certainty in our arrangements and finality in our classification. For the present we must be satisfied with the endeavour to approximate, however remotely, to the standard of perfection, and be content if satisfied that we move in the right direction; and this I believe we shall do by the arrangement which is now suggested. The active principles, then, will form the heads under which the various drugs belonging to the organic kingdom will be treated of, and their medical and pharmaceutical relations will be the leading objects for our consideration. Any one who looks at the materia medica will be, perhaps, surprised to find how many of the individuals which compose it have been placed there from their containing analogous principles, not duplicates merely, but multiples often repeated of the same agent. Nearly one fourth of the vegetable materia medica obtains its place in the list of remedies from its containing an essential oil. With this organic product very many of the natural orders abound, as is well known, with respect to the lamiate, umbellifere, the myrtaceæ, and many others. Now, although essential oils undoubtedly differ in some respects, as in flavour, in colour, in strength, and, in some degree, in effect, yet they all possess certain properties in common, are separable from the herbs which produce them by a common process, and they all have certain definite chemical relations; they may, therefore, each be grouped together. About one tenth of vegetable drugs appear to have been introduced from the astringent principle, the tannin and gallic acid, which they contain. Fixed oils, again, and resins, gums, and some other reading principles, furnish us with heads for large and important classes under which, with the nitrogenized products, it might seem that the materia medica might readily be arranged. More readily, indeed, it seemed at first sight than was found afterwards to be the case, for difficulties, in truth, presented themselves which it was necessary in some degree to get over. One drug contained several principles, and a question might fairly be raised to which its medicinal properties were to be referred. The febrifuge and the astringent properties of the cinchonas may be quoted as an

example, each being required in particular cases. In this instance repetition, they be necessary. The efficacy of other vegetable substances moreover, may again be due not to any one particular principle, but to the admixture of many, as some believe with regard to sarsaparilla, so that it may be difficult to assign to it a locality. Another objection may be urged, viz., that the effect as a remedial agent has little to do with the chemical composition of the active portion.

Purgatives may be found amongst the resinous bodies, or oils, or bitters. These are some of the points which may be urged by some as objections to my suggested classification. I shall not stop to refute them, but shall content myself with expressing my idea that, if in reality they are objections, they are much slighter than those which may be urged against other arrangements.

The classification assumes the active portion of a drug as the index of its position pharmacologically: by this plan the labour of the student will be facilitated, and by it his memory will not only be less taxed, but will be essentially aided. The investigation of the *modus operandi* of our remedies will be aided by directing attention to the active portion of our medicinal agents, and reflecting upon their qualities, their chemical agencies, and their possible catalytic influence. These ideas, let me add, are not sudden thoughts hastily adopted: they have often been stated in my lectures as desirable, and it seems to me important to advance them now, from the addition which is daily made to the list of the materia medica, by the introduction of new, or the restoration of old, remedies. The improved state of physiology and the perfection of organic analysis would also be arguments in favour of this as the appropriate time for such a measure.

In the arrangement, moreover, which it is proposed to submit regard will be had to the fact that the materia medica is usually studied in the first year of the medical pupillage, when accurate chemical knowledge cannot then have been acquired. Minute atomic calculations will be out of place. Practical utility will be more thought of than chemical accuracy of arrangement. Instead, therefore, of beginning with ultimate elements or the laws of affinity, I shall commence with the statement of the fact, that by certain modes of proceeding we can procure from vegetable peculiar definite compounds, and I shall at once consider the most important, those which produce the most powerful effects upon the living system. Such are the vegetable alkaloids. I shall next treat of the (neutral) bitter principle of plants, and then of the astringent principle—one sufficiently important to constitute the heading of a class; subsequently in order will follow such principles as are usually found naturally in combination, as resins, essential oils, and gums. Starch, sugar, and the vegetable acids will then come in juxtaposition; and, lastly, will follow the vegetable colouring matters, which, although inert as remedies, are necessary to be studied. It cannot be said that any drug is introduced into the materia medica on account of the albumen which it contains, yet we must not conclude the consideration of organic principles without regarding this, which is so invaluable as an antidote upon particular occasions—useful sometimes as a vehicle for certain remedies—valuable as a pharmaceutical, and most essential as a dietetic agent. This comprises the outline of the scheme which I venture to propose as capable of enabling me to condense greatly the subject before me, and into which I shall enter more in detail in my next paper.

A COURSE OF LECTURES ON CLINICAL MEDICINE,

Delivered in the Theatre of Queen's College, Birmingham, on
By SAMUEL WRIGHT, M.D.,
Queen's Hospital, and Professor of Clinical
Medicine in Queen's College, Birmingham, Physician
to the Queen's Dispensary, Extraordinary Member, and
Senior President, of the Royal Medical, Royal
Hunterian Medical, and Oculist's Natural
Societies of Edinburgh, &c.

secondary syphilis and syphilitic iritis; re-

capitulation of a previous observation concerning pain in the head; attempt of the patient at deception; suggestions which this part of the subject offers; circumstantial proof against the patient's statement; parallel cases; case of old-standing venereal disease denied; eruptions in gonorrhoeal cases, case of death from procured abortion, in which the patient denied to the last having made the attempt; details of the case of iritis; treatment, recovery; subsequent occurrence of conjunctivitis in the opposite eye from cold; peculiarities of iritis; dangers of adhesive inflammation, especially when affecting the eye; modes in which its mischief is produced; objects to be fulfilled in the treatment of iritis; bleeding, blistering, alkalis, mercury, belladonna.

(GENTLEMEN).—Some time ago we had an instructive case of secondary syphilis and syphilitic iritis, in the hospital. I will make its detail and comment the substance of to-day's lecture.

You will remember my speaking, in my second lecture, of the varieties of headache; and telling you, when a patient complained of shooting pains through his temples and ears, aggravated at night-time, to be suspicious of syphilis. In a few days I was enabled to offer you a good illustration of what I had said on this point.

Edward Knibbs, aged thirty-six, was the subject I allude to. On the day of his admission (late in December), I was not able to visit the hospital until between three and four o'clock in the afternoon: I found him sitting on his bed with his back to the window, and in that situation the light fell so feebly upon his face that I had a very indistinct view of it. After having put a few questions, I learned that he suffered from severe pains darting through his temples and ears, particularly when he became warm in bed. I inquired whether he had any soreness of his nose, and found that it was tender at the root, on pressure: I learned, also, that his throat had occasionally been sore for some months past. Suspecting what was the foundation of his ailment, I turned him towards the window, and then saw that his face, and his forehead especially, was covered with roundish copper-coloured patches. These, he said, had existed for about three months.

At this moment of questioning, a circumstance occurred which not only confirmed my opinion as to the nature of the patient's malady, but showed also how prone is human nature to the weakness of withholding a confession of its infirmities, from those whom it much concerns to be made acquainted with them. An old adage says,—"There are three persons whom you should never think of deceiving—your lawyer, your minister, and your doctor." The business with which it is the province of these to deal should always have the truth told of it; and yet, important as this truth is, it is rarely uttered without some attempt at qualification or concealment. At least so say legal and clerical functionaries; and our own profession can furnish ample testimony to the fact. The case of this patient is a good illustration. Directly that we obtained a fair view of his face, Mr. Bird, our intelligent resident medical officer, remarked to me, in an under tone—"a case of *lues*, is it not, Dr. Wright?" The question was asked in so low a voice, that I should have hardly recognised it, had not the train of thought which was passing in my mind aided its comprehension. It was quite impossible at the distance the patient stood, that he could have heard the precise query, yet suspecting its nature, and knowing himself guilty, he instantly rejoined—"No; nothing of the sort; never had such a disease in my life." This at once satisfied me how correct was my first suspicion. Had other evidence been wanting, the very fact of his being so ready to anticipate our opinion, and so apt and earnest in concealment, would have made me condemn him in my own mind—just as I always suspect a man to be a coward who is constantly vaunting his courage, or doubt the good principle of another who is incessantly boasting of his honesty. Pharisees and Falstaffs generally reveal their true character by the very efforts they make to conceal it.

I subsequently told this man, without any reserve, what was amiss with him, but could not get him to confess that he had ever had venereal disease in his life. He boasted how confident he had been before his marriage, and how distant since; all of which I little believed; and the next, when, on looking at his throat, I found good evidence of old ulcerations there.

I dwell upon this part of my subject, because it may be of some use to you to be told how exposed you will be to attempts at deception in the course of your future practice. It is important, not only that you be made acquainted with the liability, but that you be duly cautioned against it. Experience will astonish you with its many evidences how treacherous human nature can be, when a sense of danger or of disgrace becomes suggestive of falsehood. The utter coolness with which people will tell deliberate untruths, under these circumstances, is a pitiful curiosity in the moral history of our species. In the case I have just mentioned the man knew what his disease was, and well knew what was my own opinion concerning it, for I positively told him that it was venereal, and as such I should treat it; yet, whilst he denied the nature of his ailment, a sense of personal safety reconciled him to the taking of whatever medicines I might order. Had he been as certain as he said he was that his system was untainted, he would have left the hospital rather than have wallowed in physic which he was convinced was unsuited to his case.

I am at this time attending a dispensary patient, who has been under my care, at intervals, for the last two years, with indications, obvious enough, of secondary syphilis. At my first interview I told her what my opinion was of her disease; and I learned that such was the opinion of every medical man whom she had previously consulted; she unceremoniously told me so, but affirmed, nay, was ready to swear, that here was not the remotest foundation for our suspicions. She has suffered horrible disfigurement from her disease, for her nose is completely gone, and her face blotched, which I and might have been spared had she confessed to her early medical advisers the nature of her malady. I hinted further, that, if she were now treated injudiciously, her life might be sacrificed, and urged the possibility of this as an argument why she should tell the truth of herself. But all to no purpose: as obstinately as ever did she persist in declaring that, though she lived in a suspicious situation, her own character was beyond impeachment. To my inquiry how she obtained a livelihood, she declined giving any answer. I then informed her that my opinion of her disease was unchanged, and that I should treat her accordingly; so that, if she thought I was wrong, she had better not come under my care. To the treatment, however, she offered no objection, and, as I said, she has repeatedly been my patient for the last two years.

You sometimes meet with cases of gonorrhoea as palpable as possible, in which the patients disclaim all knowledge whatever of their infection, or the cause of it. A short time ago I was consulted by an individual for this disease, who became somewhat indignant when I told him what it was. He pompously informed me that he was married, and had the best of women for a wife: to this I merely replied with the opinion that, if his better half were to speak the truth of him, she could not return the compliment. Finding that I was neither to be persuaded nor swagged out of my belief, he confessed that appearances were very much against him, and suddenly recollected that he had been at a strange water-closet a few days previously, where, he had no doubt, the infection had been contracted. This is a very common story with such delinquents.

The specimen which I now show you, is a portion of intestine taken from a girl who died from inflammation of the bowels a few years back. The first piece of whalebone passes through the ileo-cæcal valve; the second, in the cæcum itself, passes through an ulcerous opening,

quarter of an inch in thickness. The suddenness and symptoms of the late illness led to a suspicion that she had taken some solid material to produce abortion. This was questioned on the subject, but denied the supposition most emphatically. As her danger became more apparent, and some corroborative proofs of her criminality had been elicited, she was again charged with the offence, which she again denied as solemnly as ever. When told that she was dying, and that further falsehood was useless, for her body would be examined after death, she still persisted in her statement, and actually died in its maintenance. The *post-mortem*, which was conducted by my colleague, Professor Sands Cox, showed clearly enough that the uterus had been impregnated, and that its contents had been recently expelled. The intestines, throughout, were in a state of inflammation, and in this part, as you see, ulceration had occurred. In places we found a quantity of greenish vegetable matter, which, on examination by Professor Knowles, was discovered to be saine.

I have mentioned these cases to show you, as I before said, how liable you will be to attempts at deception in the course of your practice, and how necessary, in many instances, you will find it to maintain your own opinion against declarations and specious arguments to the contrary.

To return now to the case which suggested these reflections. Satisfied of the nature of the man's disease, he was ordered the following:—

R. Decoct. sarsaparilla comp., ℥viij.; liq. potassæ, 3j.; hydrioid. potassæ, 3ss.; misce, fiat mist. cujus cap. coch. larg. duo ter die.

R. Pil. colic. comp., ℥ij.; pil. hydrarg., ℥j.; misce in massam dividendam in pilulas xij. quarum capiat ij. omni nocte.

Under this plan of treatment the man in a fortnight began to improve. His appetite became better, and he increased in weight. His nose was less tender on pressure; throat less sore; and the pains in his head did not now prevent him sleeping. The eruption, also, was much lighter in colour. On the 16th day succeeding his admission I found him with strong inflammation in his right eye. He had not been out of the hospital, and was not conscious of having taken cold. The day previously he felt a pricking sensation, and occasional shooting pains in the organ, which increased until bedtime, and kept him awake during the greater part of the night. The eyelids were red and swollen; eye watery, and intolerant of light; conjunctiva injected; a dull reddish colour extended along the lower portion of the pupillary margin of the iris, which was here slightly irregular in shape; the movements of the iris were more sluggish than natural, and during these the irregularity of structure became very evident. The left eye was quite unaffected. The patient complained of thirst and feverishness; skin hot and dry; tongue covered with a thick fur; urine scanty and high-coloured; bowels moderately open; pulse 126, small and hard. He was requested to keep in bed, and have his eye protected by a large perforated shade. He was ordered fever diet and the following:—

R. Sodæ bicarb., vini ipocac., aa. 3j.; aquæ, ℥viij.; M. f. mist. cujus cap. coch. ampla duo tertis horis cum pilula.

R. Hydrarg. chloridi, gr. iv.; ext. hyoscy. q. s. ut f. pil. viij.

Adh. emp. lyttæ pone suum dextram.

On the following day the evidences of iritis were more manifest, but the conjunctival inflammation was less, and the general febrile symptoms were diminished. The medicines were ordered to be continued; a saline aperient draught to be taken immediately, and the blister to be dressed with strong mercurial ointment.

During the following days, up to the sixth day succeeding the inflammatory attack, the patient progressed as well as could be wished: at this period there was nothing unnatural in the appearance of the eye, except a little irregularity in

that part of the pupillary margin of the iris already alluded to. There was no pain in the organ, and it bore the influence of light tolerably well. In other respects, also, the patient was better. The gums were tender and tumid; and the breath had the mercurial fetor, but there was no salivation. The calomel pills were now stopped; the blister was dressed with spermaceti ointment, and the sarsaparilla mixture given, as at first. Additionally, he took five grains each of compound colocynth pill and extract of henbane, every night.

With this treatment he continued further to progress, and, at the end of another week, the right eye was in all respects natural, both in appearance and function. The general health of the patient was also much improved, and the blotches on his skin were scarcely recognisable. In a day or two from this time he was out one evening until after dark, and got soaked in a drenching rain. The next morning he had strong febrile symptoms, and severe conjunctivitis of the left eye. The iris was quite unaffected, and the right eye continued perfectly sound. He was again confined to bed; had his feet in hot mustard and water at night; took a brisk calomel purge; had a blister behind his left ear; and the following mixture was prescribed:—

R. Sodæ bicarb., vini ipocac., aa. 3j.; tinct. hyoscyami, sp. eth. nit., aa. 3ij.; misce ft. mist. cujus cap. coch. magna duo tertis quaque hora.

He was directed to bathe his eye three or four times a day, for a quarter of an hour, with warm water. In three days all indications of conjunctivitis were gone; both eyes were healthy-looking, and performed their functions well, and every febrile symptom had disappeared. We then returned to the sarsaparilla mixture, and the patient had, additionally, five grains of compound colocynth pill every night, for his bowels were constantly needing stimulation. From this time we had no drawback, the man rapidly gained health and strength; had an excellent appetite and digestion; slept well, and was quite free from the pains that troubled him on his admission. His skin also became perfectly cleared of the copper-coloured patches that disfigured and characterized it when he first came in. You remember his stripping on the occasion of our last visit, and there was not a suspicious spot to be found on him. On the 10th of February he was discharged cured.

Iritis, whether syphilitic or simple, is a very formidable disease to treat, and should always be met by very determined and sustained measures. The organ seized, and the nature of the seizure, demand that no temporizing or merely palliative means be used. The great feature of iritis, and that which makes it chiefly to be dreaded, is the fact that the inflammation is of the adhesive kind. Under any circumstances, this variety of inflammation is to be regarded with anxiety; but the more especially so, when the organ it visits is peculiarly obnoxious to its worst influences. This is the case with the delicate texture of the eye. I am alluding to. Adhesions of structure, naturally met, have more or less influence with the due performance of their functions—thus, when there are pleural adhesions, there is some peculiarity or other of respiration; when pericardial, the circulation is often at fault; when intestinal, there is frequently obstinate constiveness. Yet all or any of these may exist, and the subject of them be in tolerable health, and his life be prolonged to an average period of existence. With inflammation of a delicate tissue like the iris, the case is somewhat different. It runs a rapid course, and is either out short before mischief comes, or commits that mischief very quickly. True, it is not destructive of the life, but it is liable to be destructive of the functions of an organ that eminently ministers to the comforts, conveniences, and pleasures of life. To lose our eyesight, is to be debarred of many of the opportunities that make existence a happiness. The peculiar character of iritis renders it probable that, if the disease be not

seen checked, an impairment or destruction of vision will soon be its consequence. As I have said, the inflammation is of the adhesive kind; and the effused material is apt to be parts that ought to be movable, or to fill others that ought to be open. Thus, the movements of the iris may be prevented by the effusion, partially or wholly, of lymph into its texture; or, as to the uvea, attaching it more or less to the crystalline lens; there may be effusion into the anterior or posterior chamber, or both, or the pupillary space may be completely filled with lymph, constituting complete blindness; the crystalline capsule may have an adventitious deposit upon it; the posterior tunics may become altered from an extension of the inflammation; and other various disastrous effects may easily be the issue of this said ailment.

The great object in treating it, is to lessen the violence of the inflammatory action, and change the character of its products. In effecting this, it is of paramount consequence to attack the disease at its commencement; if, on the earliest manifestations of iritis, remedial means be used, it is easily restrained; if it have advanced some length, its restraint and reparation become proportionately difficult. A few weeks ago I attended, in consultation with Mr. Middlemore, a young gentleman, the subject of syphilitic iritis. We had to keep him under the influence of mercury for a month, and confine him to the house for more than double that time. It is probable that much less treatment would have sufficed, had he followed the advice first given him, to keep at home, and submit to medical discipline at once, instead of trifling with the disease until it became all but intractable.

In treating iritis you ought to remember two things—first, that it is inflammation; and, secondly, that it is attended with the effusion of coagulable lymph. These conditions you have especially to combat. The first you answer by direct depletive means—leeching, cupping, or bleeding from the arm if the inflammation be strong enough to require it. If it be met at the commencement, as in the case you saw in the hospital, blistering behind the ear, or at the back of the neck, is generally sufficient. It is of importance that the blistered surface be kept open; it is a constant check upon congestion and inflammatory action near it. Additionally, low diet, saline aperients, and febrifuge medicines, as we ordered for Knibbs, are valuable auxiliaries. Patients will often solicit unsuitable food or drink; never give it them. It is important to keep the light from the affected eye. This is best done by a shade, which does not keep in the heat at the same time. Fine gauze, wire, or green pasteboard, perforated with small holes, such as milliners use for the foundation of bonnets, is the best shade you can use.

To alter the product of inflammation in iritis—that is, to render the lymph less prone to coagulation—is one of the greatest points in the treatment of this severe affection. To this end alkalis and mercurials are invaluable contributors. They lessen the coagulability of the blood, and therefore diminish the plasticity of the effused lymph. In the treatment of iritis, amongst other accessory remedies, push these, and continue the use of them, until you find the disease begin to give way. It is said that mercury will both cause and cure iritis. The former I should very much doubt; and as for the latter, the drug is not a direct specific, as some people say, but merely produces its good effects by the means I have mentioned. Belladonna, so much vaunted in this affection, I think is only of use in aiding the action of the iris; and this I think it can only do after the subsidence of inflammation. Whilst this lasts, I feel persuaded that its services are useless. In the case of Knibbs we did not employ it, for the iris recovered its regularity, as I thought it would, without interference. The subsequent conjunctivitis of this man's left eye, the iris being unaffected, is a curious and, I suppose, unaccountable circumstance. I saw him a few days ago, and learned that he has had no return of his ailment.

ON THE PHYSICAL PHENOMENA OF LIVING BODIES. (a)

By Professor MATTEUCCI, of Pisa.

PART I.
INTRODUCTION.

Living bodies are endowed with the general properties of all natural substances. No one, not even the most uncompromising vitalist, has ever ventured to dispute that organized living matter occupies space, and is impenetrable, divisible, and porous. How can it possibly be admitted that heat, electricity, light, chemical affinity, should act upon living bodies in a manner totally different from that in which they are found to act upon other natural bodies?

Some highly-esteemed physiological works of the present day contain still, tables pointing out the differences, nay even the positive contrasts, presumed to exist between organic and inorganic bodies. It would be a mere waste of time and argument to attempt to demonstrate that many of these pretended differences and contrasts are of little or no value. Animals and plants increase by *intussusception*; minerals by *juxtaposition*; or, in other words, in the former, growth takes place by *internal*, in the latter, by *external*, juxtaposition: for this reason that organized bodies secrete *within* them the dissolved elements of the new formations; whilst, on the contrary, inorganic substances find these elements placed at their *outside*.

During life an incessant struggle is going on between the physical forces on the one, and the vital forces on the other; death is the triumph of the former over the latter. But is this fact sufficient to prove that the vital and physical powers are essentially distinct from one another, and antagonistic in their mode of action? Would it be correct to assert that the different parts which, united, constitute an arch, are endowed with a force opposed to that of gravity, simply because they do not fall?

Extent, impenetrability, divisibility, and porosity, the general properties of all natural substances, are inherent likewise in organized living bodies. Organic substances, plunged into water or other liquids, exhibit the same faculty of imbibition as sand, pounded glass, porous bodies, and substances formed of capillary tubes &c. This property of living bodies is of the very highest importance. In a great number of animals, life (or, more properly speaking, the vital functions—the *manifestation* of life) may be suspended for a long time with impunity; such apparently lifeless animals, when brought into contact with water, which they have the faculty of imbibing, return to life and resume their usual movements. Who knows not the beautiful experiments of the illustrious SPALLANZANI on the rotiferous animalcule? Tendons or membranes, dried into a hard and horny mass, do not much look as if they had formed part of an organized body; yet, plunge them into water, and, in proportion as they get soaked, they will gradually recover the softness, suppleness, and elasticity which originally enabled them to perform the functions assigned to them in the living body.

Elasticity is a property of living bodies as well as of all other natural substances. Thus, for instance, a piece of intestine, or an artery, admits of being more or less stretched or compressed. Let the respiratory organs be removed from a corpse, and a tap fixed to the trachea: the opening

of the tap will cause the lungs to collapse; the reintroduction of air, on the other hand, will cause them to swell and dilate again.

It would be very erroneous indeed to suppose these diverse organs capable of performing their respective functions in the living body, independent of the elasticity of the intestine, artery, and the parenchyma of the lungs. Let that elasticity be destroyed, and the functions of these organs will be annihilated, or, at all events, altered.

The solid, liquid, and gaseous parts of living bodies are subject to the same laws of gravity as all other natural substances. It would be altogether impossible to explain the functions of respiration and absorption, without reference to the properties of the solids, liquids, and gases of the organic economy, and to their conditions of equilibrium. If we submit any organic substance to the requisite degree of heat, we observe the disengagement of gas, the escape of aqueous vapour; we see the carbon and hydrogen burn in the air, producing carbonic acid and water. We frequently find organic matter to harden and shrink at first upon the application of heat, instead of melting and liquefying, as happens usually in the case of inorganic bodies; but surely no one will venture to attribute this different comportment with heat to the influence of a vital action, since, when these phenomena are observed, life has been long extinct in the organic matter exhibiting them.

All these effects are owing to a particular structure and the physico-chemical properties of the elements composing the organic tissues. In fact, organic substances submitted to the action of heat lose, in the first place, the water which they contain, and this expulsion of water commences in that part which is the most directly exposed to the influence of the heat; the loss of water causes the substance subsequently to curl up into the shape of a scroll, just like a piece of paper that has been moistened more copiously on one side than on the other, the wettest and, consequently, most expanded and elongated side occupying the convexity of the new shape thus acquired.

Organic substances frequently contain albumen, which the action of a strong heat causes to coagulate; their elements separate in the gaseous state, to form more simple and, consequently, more permanent compounds.

The electricity of tension pervades organized bodies; it spreads through them with greater or less facility according to their respective degree of humidity; the electric spark, passing through them, volatilizes them, burns them, reduces them to ashes. The electric current, transmitted through the fluids of living bodies, operates the decomposition of the salts contained in them; the acids collecting at one, the bases at the other, pole. Albumen coagulates at the positive pole, whither the oxygen and an acid frothy liquid likewise repair; the hydrogen goes to the negative pole, together with an alkaline fluid.

Every one knows that the luminous rays, in traversing the humours of the eye, deviate from the straight line, both divergently and convergently, according to the respective different density of the humours, and to the conformation of the parts which enclose them. The eye presents, in this respect, the same phenomena as are observed in a dioptric instrument.

Finally, the elements which compose living bodies obey invariably the general laws of affinity. Chemists can detect and separate them by the ordinary methods of analysis. Let them be subjected to the action of chlorine, bromine, or iodine, and the first element that separates will be hydrogen, which then combines in *status nascentis* with these metalloids to hydrides. All oxidizing agents of any strength will convert organic matter into acids.

But do all these facts, taken collectively, justify the conclusion that all the phenomena presented by living bodies may be explained solely by the general properties with which living organized matter is endowed, in common with all other natural substances, and by the action of

the great physical forces—heat, light, electricity, attraction? Most assuredly not. Such a conclusion would be as far from the truth as the notions of those physiologists who have denied, and continue still to deny, to living bodies the possession of these general properties, and who look upon them as altogether removed from the influence of physical agents.

If we examine even what may, perhaps, not inappropriately be termed the *most physical*, the *most chemical* phenomena presented by living bodies, we find that the mode of action of the chemical and physical agents upon matter in the living organism differs considerably from that in which the same agents act upon inorganic matter; these differences are altogether inexplicable in the present state of our knowledge regarding the laws that govern these forces. Does not even the phenomenon of vision, which might be called perfectly and entirely physical, present certain peculiarities which have hitherto baffled all attempts at explanation? The most recent discoveries of science enable us, indeed, to explain the distinctness of vision at all and every visual distance, and the absence of coloured fringes; but do the physical laws afford us any explanation how it happens that our vision presents to us objects single, and in their natural position, from a double and reversed image? Again, if we look at the phenomena of hearing and voice, which seem simply effects of particular vibrations of the air, propagated through solids, according to the general laws of acoustics; how many peculiarities do they present, for which these general laws will not enable us to account? Science offers no perfectly satisfactory answer to any of these questions.

The chemical action of light, which decomposes the carbonic acid, carries the carbon, allied in new combinations to other elements, into the internal economy of the plants, disengages from the latter oxygen, and effects thus what the most powerful chemical affinities are unable to operate—is surely different from that chemical action which effects the decomposition of certain oxides, or certain metallic chlorides—operations for which even the most feeble chemical actions suffice.

The singularity of the phenomena elicited by directing an electric current upon the nerves of any living animal, shows most clearly the immense difference that exists between the effects of the great forces of nature when acting upon living and organized bodies, and when acting upon dead and inorganic matter.

The cause of these great differences in the mode of action of physical agents upon living bodies, and upon other natural substances, is indeed a problem of the highest and most primary importance; but the present state of our knowledge leaves us, unfortunately, without any positive and satisfactory solution of this problem. We must not, however, on that account relinquish the analogies afforded to us by physics: a ray of light passing obliquely through a piece of glass, or a body of water, deviates from the straight line; if, on the contrary, it encounters a crystal of carbonate of lime, we see it separate into two rays, each of which deviates in a different degree. The cause of the difference of these phenomena lies in the diversity of the physical structure presented by the glass and the crystallized carbonate of lime, and, perhaps, likewise in the difference of the chemical nature of the respective molecules of the two substances. But this much is certain, that these modifications of the luminous ray are owing rather to the diversity of structure or to the particular disposition of the molecules, than to any difference of chemical composition. We know, in fact, that greater or less compression, in different directions, modifies and alters the action of glass upon the rays of light: the chemical composition of the glass remains here entirely unchanged, and the modification of the luminous rays must therefore be considered here as altogether independent of this chemical composition.

Who could confound an organized with an inorganic body? Let us look at the lungs, for

(a) TRANSLATOR'S NOTE.—The Italian work of Professor Matteucci (pretty generally known through a faulty French translation), though much decried for its speculative excesses and extreme wordiness, contains much matter which, properly ascertained, possesses interest for the physicist and the medical practitioner. Instead of, therefore, of following a bad model, and making a "very imperfect" translation of an *imperfect* translation, it is here proposed to give a *new abstract* or abridgment of the original, publishing at large those portions only which are of real interest. The series will not comprise more than eight papers.

stances. In the groups of closed vesicles, of different sizes, collected and arranged in an irregular manner, there is surely something essentially different from an aggregation of polyhedral particles, united into a crystal. To assert, with certain micrographers, that organization is crystallization proceeding in a liquid which the first crystals formed have the faculty of imbibing, is equivalent to admitting that the structure of a stalactite is the same with that of the parenchyma of the lungs and liver.

Molecules composed of three elements, at the least, and consisting each of a very great number of elementary atoms, must necessarily form chemical systems of which the affinities differ from those presented by molecules composed, in most cases, of only two elements, and consisting of a smaller number of elementary atoms; and although the general chemical law, that compounds become less stable and permanent in proportion as the number of elementary atoms increases, explains sufficiently the tendency of complex organic bodies to resolve themselves into more simple compounds—and chemistry affords us, moreover, many instances of the same tendency in certain inorganic compounds which, in their composition, present great analogies with organic bodies—yet, notwithstanding, the laws of inorganic chemistry are manifestly insufficient to account satisfactorily for the chemical phenomena of life. We must, therefore, conclude that the molecular organization and structure of living bodies exercise a considerable modifying influence upon the action of the divers physical and chemical agents.

Moreover, the ordinary laws of affinity fail to explain those peculiar chemical phenomena which are termed actions by contact, or *catalysis*. In most of such catalytical processes we find that a certain body, usually present in very small quantity, causes, when brought into contact with other compounds, considerable transformations either in the chemical composition or physical properties of the latter, without itself suffering the slightest modification. The various kinds of fermentation belong to this class of phenomena. The number of such catalytical actions in living bodies is immense. We can effect them likewise in our laboratories; they are of the same nature with that exercised by highly divided platinum upon a mixture of hydrogen and oxygen, or of highly divided silver upon oxygenated water.

The cell may be looked upon as the elementary organ—the molecule of organic bodies. Now, the single phenomenon of endosmose (which belongs entirely to the domain of the physical forces) enables us to explain the mechanism of the life of the cell, and to account for the manner in which those materials which serve for its nutrition are absorbed, whilst other matters are eliminated.

The phenomena of light, heat, and electricity are produced in the organism of living bodies by the play of the same physico-chemical actions which give rise to these phenomena in inorganic substances. But is all this knowledge, are all these facts and analogies, sufficient to lead us to hope that we shall arrive at a complete and satisfactory explanation of all the phenomena presented by living bodies? For the present, at all events, any such expectation would be illusory.

Will any of the physical forces enable us to account for the secretion of urine in the kidneys, or of bile in the liver? Will the play of chemical affinities, however much modified we may imagine it to be by the particular structure of the organs, and even by the intervention of catalytical action, enable us even so much as to guess the manner in which the divers organs operate the separation and transformation of the constituent parts of the blood, from which they have to draw the necessary supply to repair their continual losses, and in which all the organic elements are intermixed, partly suspended, and partly dissolved? What might not be said in this respect on the functions of the nerves, and on generation!

The whole of the preceding facts, taken collectively, lead to the following general conclusions:—

1. That living bodies possess the general properties of all natural substances; that these properties exercise a certain and positive influence in the production of the peculiar phenomena of living bodies; and that, consequently, we ought not to neglect or overlook them, when endeavouring to explain these phenomena.

2. That the great physical agents—heat, light, electricity, molecular attraction—act upon living bodies as well as upon all other natural substances, and that the action of these physical forces must necessarily exercise a certain influence upon the nature of the functions peculiar to these bodies.

3. That these forces, when acting upon organized matter, sometimes act differently from their general mode of action, and that this difference is owing to the diversity of structure and chemical composition of organic bodies.

4. That living bodies present, moreover, numerous phenomena which are termed vital; that these vital phenomena are of the very highest importance; and that, in the present state of science, we are entirely unable to see how the physical agents, even though modified in their action by the organism, can intervene in their production.

To comprehend the phenomena presented by the living organism, it is as necessary, therefore, to consider the physico-chemical phenomena of living bodies, as it is to attend to the revelations of experimental physiology. The third class of facts, pointed out above, furnishes the requisite link between these two branches of knowledge. The study of the modifications which the organization of living bodies operates in the ordinary action of the physical agents, requires the concurrence of both physics and experimental physiology.

With regard to the fourth class of phenomena, the term *vital phenomena* has here been selected in preference to that of *vital force*. The difference between these two terms is indeed most material.

Had Newton's whole merit simply consisted in his having bestowed the name "attraction" or "attractive force" upon the force which governs the marvellous system of the celestial mechanics, his name would long since have sunk into oblivion. But this illustrious philosopher demonstrated that attraction acts in a direct ratio to the masses, and in an inverse ratio to the square of the distance; and revealed thus the eternal laws of that force. It is this brilliant achievement that has rendered his name immortal.

To talk of vital forces, to give a definition of them, to interpret phenomena with their assistance, and to be ignorant all the while of the laws which govern these supposed forces, is mere unmeaning verbiage, altogether void of practical utility—nay, worse still, it tends to beguile and lull the mind, and to stop the search after truth. To say that the liver separates from the blood the elements of the bile, by means of the vital force, is simply equivalent to saying that the bile is formed in the liver. But a dangerous illusion may be created here by the introduction of the term "vital force," since, although in reality explaining positively nothing, yet it seems fully to explain the whole process of the formation of the bile.

PART II.

MOLECULAR ATTRACTION—CAPILLARY ATTRACTION—IMBIBITION.

Every one knows that living bodies could not continue to exist without a constant supply of new substances from without. These substances, mostly solid, are transformed and reduced to the liquid state by certain processes of the organism; in this form they penetrate into particular cavities, whence they are subsequently expelled, after having undergone further transformations. It has been stated already that the porosity of the tissues of living bodies enables them to imbibe the liquids with which they may come into contact. In order, therefore, to comprehend the phenomena of absorption and exhalation, it is indispensable that we should consider and examine

the part which capillary attraction, imbibition, and endosmose perform in these processes.

To begin with capillary attraction: the principal results of the observation of capillary phenomena may be embodied in the following propositions:—

1. When a body is plunged into a fluid, the latter is either raised or depressed around it, and presents thus, at its point of contact with the immersed solid, in the first case a concave, in the latter a convex, surface. Glass immersed in water is a familiar instance of the former, glass immersed in mercury, of the latter case. In the former case the immersed body is said to be *wetted*.

2. The joint immersion of two bodies in a liquid causes the latter either to rise or to sink between them, according as they are wetted or not by it. It suffices for the manifestation of this phenomenon that the immersed solids be placed sufficiently near one another to bring the two curved surfaces formed by the fluid into contact. The elevation of the fluid above, or its depression below, its level is in inverse ratio to the distance between the two solids.

3. If a glass tube, open at both ends, be plunged into a fluid, the latter will (according to its respective nature) either ascend in the tube above, or sink in it below, its own level; and this elevation or depression of the fluid will be the greater, the smaller the diameter of the tube. If we compare the elevation or the depression of the fluid in a cylindrical tube with that observed between two glass plates immersed in the same respective fluid, and placed at a distance from one another equal to the diameter of the tube, we find that the elevation or depression of the fluid in the tube is double that between the plates. Liquids susceptible to wet the glass, such as water, for instance, ascend in the tube and adhere to the glass; whilst liquids that do not possess that faculty sink below their own level in the tube. In a tube of one millimetre (a) diameter, water rises thirty millimetres above, whilst mercury is depressed thirteen millimetres below, their respective level.

If we reflect upon the fact that the vacuities, interstices, and capillary tubes of animal and vegetable tissues are from 1-100th to 1-200th of a millimetre in diameter, we can have no hesitation to admit that capillary action must exercise considerable influence upon the functions of these tissues.

4. The concave surface of the raised, and the convex surface of the depressed, fluid belong respectively to a hemisphere, the diameter of which will be found equal to that of the tube.

5. A drop of water introduced into a conical glass tube resorts to the most narrow part of the tube, whilst a globule of mercury, on the contrary, resorts to the widest part.

6. The preceding phenomena are entirely independent of the volume of the solid body immersed in the liquid, whence it follows that the thickness of the walls of the tube is likewise without influence upon them.

7. These phenomena manifest themselves with equal freedom in the air, whether at the usual, or at a higher, or at a lower pressure, in *vacuo*, and in any gaseous medium whatever.

8. All bodies susceptible to be moistened (whatever their nature in other respects) furnish the same results, provided that, previously to their immersion in a liquid, a layer of the same liquid be made to adhere to them.

9. The elevation or the depression of the liquid column within a tube diminishes (for the same liquid and the same tube) according to the temperature of the liquid.

10. The elevation and depression of liquids are independent of the density of the latter. Thus, taking the elevation of water in a tube = 100, that of alcohol will be = 40, of essence of lavender = 87, of a solution of sea salt = 88.

11. Two bodies floating on a liquid, within a certain short distance only from one another, are attracted towards each other, and unite, provided that either both or neither are susceptible of being

(a) A millimetre is considered equivalent to 1-26th of an inch.

moistened by the liquid. But they seem to repel one another if only one of them is moistened.

12. To whatever height a liquid may rise in a capillary tube, it will never run over at the upper aperture. To comprehend the reason of this, we need simply reflect that the surface of the liquid column raised in the capillary tube is invariably and constantly concave; and if we take a bent tube, and fill the one arm of it with water, sufficiently to render the surface of the column first horizontal, and finally convex, the column in the other arm will continue to present a concave surface, and will stand at a higher level than that in the arm filled to the brim. Thus, the moment that the surface of the liquid column becomes convex, a force of depression develops itself in the capillary phenomena. To suppose that the dripping of water from the pendent end of a perpendicularly-held cotton wick, saturated with that fluid, is caused by capillary attraction, would be a grievous mistake indeed; let the wick be held in a horizontal position, and the dripping will immediately stop.

To guard against wrong application of the capillary phenomena to the processes of the animal economy, it is necessary to bear in mind that a space completely filled with liquid is incapable of exerting any capillary action; that the action of a capillary tube upon liquid is owing less to the material of the tube than to the nature of the liquid that moistens its internal surface, and, finally, that capillary attraction never causes liquid to run over at the upper aperture of capillary tubes.

The phenomena of imbibition, of hygroscopicity, &c., are, in general, of the same nature as the preceding, and depend upon the same force. A piece of sugar, a cotton wick, a heap of sand, ashes, or sawdust, when placed in contact with water, or any other liquid that possesses the faculty of wetting them, draw that liquid speedily through the whole of their mass; or, in other words, absorb or imbibe it. Certain organic tissues, cartilages, tendons, &c., that have been dried into a hard and horny mass, when immersed in water, absorb the latter and regain their original softness, suppleness, and elasticity. The same effect is observed in the case of the rotiferous animalcule, which is restored to life and motion by being moistened with a drop of water. It is by imbibition that the filtration of fluids is effected; the solid particles which fluids contain in suspension remain in the filter, whilst the fluid itself is imbibed by the substance of the latter. A drop of chocolate or ink falling upon a piece of cloth or filtering-paper produces a dark central spot, surrounded by a less deeply-coloured border; the same phenomenon is observed in effusion of blood under the skin; the colouring matter of the blood occupies the centre of the stain, the serum is found at the margin.

In these phenomena of imbibition we have to consider, in the first place, the force of adhesion between the liquid and the surfaces of the solid particles in contact with it; and, in the second place, the true capillary action—for there certainly exist in the sugar, in the heaps of sand or ashes, &c., and in the organic tissues, extremely minute cavities more or less tortuously ramified in the interior of the mass.

The author has made, in conjunction with Professor Cima, several interesting experiments on the subject of imbibition. Several glass tubes, of about two centimetres diameter, were filled with very white, perfectly dry, and most finely sifted sand; the lower end of the tubes were closed with a piece of linen tied round the tube; the sand was introduced through the upper aperture, without shaking the tube, in order to guard against unequal compression of the mass. Six tubes so prepared were plunged at the same moment into six different liquids of 12° Centigrade (53·6 Fahrenheit). The imbibition of the liquids in the tubes continued for ten hours, proceeding rapidly at first but decreasing gradually more and more in energy, in proportion as the liquid approached the point at which it ultimately stopped. The tubes were immersed in the several liquids to the depth of about half a centimetre,

and care was taken to replace the fluid occasionally, so as to maintain a uniform depth of immersion throughout the process.

The subjoined table shows the highest elevation to which the several liquids rose. The saline solutions were all of the same density, viz., 10° of Baumé's areometer:—

	Millimètres.
Solution of carbonate of soda ..	85
Solution of sulphate of copper ..	75
Serum ..	70
Solution of carbonate of ammonia ..	62
Distilled water ..	60
Solution of sea-salt ..	58
Milk ..	55
White of an egg mixed with an equal volume of water ..	35

This table will give some notion of the immense difference in the respective power of liquids to be imbibed: thick solutions of gum, boiled starch, oil, resist imbibition nearly altogether; concentrated saline solutions, and all fluids holding in suspension highly-divided solid particles, are likewise but feebly imbibed; in the latter instance the imbibition acts like a kind of filtration. This fact may be of some importance to the physiologist and physician, since it may assist in the appreciation of the different properties of the blood according to its density. Indeed, in certain diseases the density and viscosity of the blood are greatly diminished; in such cases serous infiltrations take place; the same infiltrations, and arising from the same causes, are observed after great losses of blood.

Experiments made with alcohol at 36° Baumé, and with distilled water, gave the following results:—

	Tube filled with sand. With pounded glass. With sawdust
Alcohol rose 85 mil. ..	175 mil. .. 125 mil.
Water .. 175 ..	182 .. 60 ..

These results show that alcohol rises less high than water, as far as sand and pounded glass are concerned, which is in perfect accordance with what takes place in capillary tubes. Two tubes, the one (1) containing double the quantity of pounded glass as the other (2), were immersed in water. In 1 the liquid rose to 70 millimètres, in 2 to 107 millimètres. It is not easy to explain the proportion between the respective elevation of the fluid in the two tubes; it is natural, however, that the liquid should rise higher in the tube containing the larger amount of matter, since this offers, of course, a larger surface of attraction, and the capillary cavities are of smaller diameter.

The animal and vegetable tissues furnish abundant proofs of this fact: the greater and more extended the surface they offer to liquids, the more readily they imbibe the latter.

The temperature exercises considerable influence upon the degree of imbibition. Two tubes filled with sand were immersed in water; the temperature of the one tube (1) was 55° Centigrade (131 Fahrenheit), that of the other (2) 16° Centigrade (59 Fahrenheit). The results were as follows:—

	Elevation after 70 seconds.	Elevation after 11 minutes.
1.	10 mil. ..	175 mil.
2.	6 ..	12 ..

Now, we know likewise that absorption in animals (no matter whether through the skin or in the internal organs) proceeds the more rapidly the hotter the liquid in contact with these organs.

Imbibition proceeds equally in dry and in moist air. *In vacuo* it seems at first to proceed with greater rapidity than in the air; but this difference ceases and becomes equalized after a few minutes.

One would fancy that, by the action of imbibition, a liquid might be raised to any height; for, considering separately the imbibing action of every individual layer in a column of sand, ashes, &c., immersed at one end in a fluid the level of which is constantly maintained at the same height; one would be led to reason that, after the imbibition of the first layer, the particles inmediately above withdraw a portion of the fluid from it for their own imbibition, which

lost the first layer supplies again from the liquid mass in immediate contact with it; the third layer acting with respect to the second in the same manner as this acts with respect to the first, and so forth throughout the whole mass of the column, no matter what its height. Experience, however, does not confirm this reasoning: the liquid rises rapidly at first, then the ascensional movement slackens, and ceases finally altogether when arrived at a certain point. That this cannot be attributed to evaporation that might be assumed to take place in the upper layers of the column, is sufficiently clear from the fact that water rises exactly to the same height in a column of sand when the surrounding atmosphere is charged with aqueous vapour, as when it is perfectly dry. There seems to be no other way to account for this limit to imbibition, except to admit the existence of small channels throughout the whole length of the column; and thus it would seem that capillary action intervenes here, besides the adhesion of the liquid to the surface of the grains of sand.

It is impossible not to perceive that imbibition performs an important part in the movement of the juice of plants, and in the phenomena of the capillary circulation of the blood of animals; we shall presently see that living plants and animals, when immersed at any point whatever in a saline solution (the presence of which may be subsequently readily detected by reagents), are speedily penetrated by it throughout the whole of their parts. It will be sufficient here to mention the experiments of Hales, and the more recent ones of Boucherie; the latter experimentalist saw a poplar tree, about ninety feet high, absorb in the space of six days the enormous quantity of near eighty imperial gallons of a solution of pyrolignite of iron.

Hales made certain experiments for the purpose of measuring what he termed the force of aspiration of pulverulent bodies and stems of trees. For this purpose he used a large glass tube, closed at the upper end, filled with ashes or most finely pounded minium; the other end he closed with a perforated cork, to which he fitted a narrow glass tube, about three or four feet high. He filled the latter tube with water, and inverted it rapidly over mercury. He saw the mercury presently begin to rise in the tube, and in one experiment this substance rose seven inches, which is equal to a column of water of eight feet.

In other experiments he substituted the stem of a tree for the ashes used in the first, and he obtained the same results. He considered this phenomenon to be dependent on a particular force, to which he assigned the name of *aspirative force*, or force of aspiration. However, certain experiments made by the author, and in which he had recourse to the creation of a vacuum above the ashes, stem, &c., at one, and above the mercury in the trough at another, time, supply a more simple and satisfactory solution to the problem presented by this phenomenon. The experimentalist found that the creation of a vacuum above the ashes, &c., caused the mercury to rise still higher in the tube, whilst the vacuum over the trough brought the mercury immediately and completely down from the tube. It is indubitable, therefore, that the ashes, &c., form above the column of water, a wall or partition which performs exactly the office of a close tube; in short, Hales' apparatus is a barometer, and the phenomenon of the ascension of mercury resolves itself accordingly into one of atmospheric pressure.

A very curious fact deserves mention here. If a leafy branch of a tree be substituted for the tube filled with ashes, &c., the column of water will continue to rise the same as in the other experiments of Hales. It would appear, then, that the leaves are susceptible to exhale the aqueous vapour without discontinuing to perform the office of a barometrical tube. Magnus seems to have obtained the same result with a tube closed at the upper end with a piece of membrane. It is probable, however, that the phenomenon in these instances has its limits, from

the supervening disorganization of both leaves and membrane.

A few words may be added here regarding certain experiments made with a view to produce, by the simple play of the capillary forces, and of molecular attraction, the effects of chemical affinity. If we reflect that the elevation which a liquid (of whatever nature) reaches in a capillary tube is constant, that imbibition is attended with greater or less evolution of heat, as Pouillet's experiments have proved; that it is attended, moreover, according to Becquerel, with disengagement of electricity; and, finally, that capillary attraction acts only at extremely limited distances, and between the molecules of bodies—we cannot but come to the conclusion that this force combines the principal characteristics of chemical affinity. Doebereiner observed, that from a mixture of water and alcohol, enclosed in a bladder and exposed to the air, the water alone escapes; the cause of this phenomenon is, that the water is more readily imbibed by the membrane than the alcohol, and is thus enabled to escape by evaporation. The fact mentioned by Berzelius, viz., that salt water, filtering through a long tube filled with sand, runs off, freed more or less completely from the salt which it contained originally. The author filtered salt water through a tube about 24 feet long, and filled with sand; the density of the water flowing off from the lower aperture of the tube was to that of the solution originally introduced at the upper aperture = 0.91. But this proportion is not maintained, and after the lapse of a certain time the saline solution is as dense at its exit from the tube as it was at its introduction. This proves that the decomposition of the saline solution takes place during the first action of contact between it and the particles of sand in the tube.

A solution of carbonate of soda was made to pass through a tube about nine feet long, and filled with sand; the result proved the reverse of that in the former case. The density of the liquid at its exit from the tube, as compared to its original density, was = 1.005.

These phenomena are of great importance, inasmuch as they may assist us to account for certain functions of living bodies, for which capillary and molecular attraction afford no sufficient explanation.

ORIGINAL CONTRIBUTIONS.

OWEN'S OSTEOLOGY OF FISHES.

By DR. WILLIAM MACDONALD, J.R.S.F.,
Fellow of the Royal College of Physicians in Edinburgh,
and Member of the Linnean, Wernerian, and other Societies.

There are few characteristics which more strikingly exhibit the advance of science of late years than has been afforded by the rapid and somewhat multifarious flow of publications of every name and character—from the bulky *pound encyclopedia* to the voluminous penny magazines and other attractive compilations “for the million.” The cheapness and almost endless facility of embellishment which the lithographer and, still more, the wood and steel engraver have enabled the industrious members of the great publishing clique to produce and reproduce the same materials under very Protean aspects, and although in some instances the copies, for ignorance or want of attention, have been engraved without being reversed before the explanatory letters were added, the illustrations are, generally speaking, if not examples of the highest art, yet of considerable use to the student and general reader. The earlier advance of our continental neighbours in the different branches of natural science, especially in zoology and zootomy, has been a fertile source of “information for the people,” and the various “manuals,” “elements,” and systems of zoology which have of late years been published in this country have either been professed translations, or (what is more to be regretted and denounced) have appeared with the pretension of originality without

acknowledgment of the source from whence they have been plundered.

Of late, natural history has taken a more scientific turn, and the very beautiful productions which are in course of publication by Van Voort, while they have proved attractive to the general reader in the boudoir and drawing-room, have, at the same time, been highly useful to the naturalist. The older method, of founding systems of zoology on the scale and feather system, is being replaced very generally by adopting the surer basis of zootomy or comparative anatomy. Of late even professorships of comparative anatomy, as a separate branch, are being established in all the newer collegiate institutions, though the rust of antiquity has prevented their establishment in the older seats of learning and science; but even in these we are not without hope that something may be accomplished from what we have lately witnessed in the University of Edinburgh, where the newly-appointed and enthusiastic professor of anatomy has a large class of attentive students gathered around him without any juncture from the senate, and we recollect well, before lectures upon natural history were introduced into the curriculum prescribed by the University, that the excellent professor was attended by hundreds of the best class of students, and that his lecture-room was then crowded to overflow, and thus he was enabled very early to diffuse very extensively a taste for natural history generally, but more particularly for mineralogy and geology. But what is the state of attendance now? From the blighting effects of the prescribed curriculum of the medical faculty, we learn that scarcely more than twenty or thirty attend his lectures. The increasing interest, however, which attends the delivery of lectures has naturally produced the publication of these in a separate form, either without sanction, as in the case of the *Lancet*, where the lectures of Professor Grant first appeared, or by authority, as in the volume lately published by Professor Owen, from notes taken during his oral lectures, but afterwards corrected and extended by himself. This is the second volume of lectures on comparative anatomy which have been delivered before the College of Surgeons of London by the distinguished and highly-gifted professor who is intrusted with the care of the valuable Hunterian Museum, who, from the important position which he holds in science and public estimation, and the devotion with which he applies his energies to the advance of science, must stamp any work emanating from him with a standard importance. We have, therefore, been induced to analyse the second volume, as we think there are views of the analogy of the different organs throughout the animal scale which are at least not quite made out on sound philosophical data, and are not always consistent with his own views as scattered throughout the volume. On the present occasion we restrict ourselves to “the Osteology of Fishes,” which is adopted as the basis of illustration in the pleasing study of analogy.

It is the natural attendant on the early progress of any branch of natural science dependent on observation and description, that there should be considerable confusion in the nomenclature, from the different views under which the subject may be studied by observers carrying on their investigations independently and at a distance from each other. There is, perhaps, no branch connected with natural history where this has had a worse effect than in comparative anatomy, and especially in pointing out the various analogies. We therefore are the more anxious to notice what we consider erroneous in this respect in the work before us, which is likely to become a standard text-book. As the study advances, the necessity of a uniform nomenclature will be more and more felt, as great confusion arises from different names being too often applied to the same part. We often find opposing and contradictory accounts given by different authors. Perhaps the greatest cause of error arises from a rigid adherence to the analogies long ago

the early authority, whose labours are for themselves, and for

entertain the very highest respect; but we find that the power of their great names acts in retarding the advance of a science which they devoted their life and leisure to promote. We feel ourselves constrained to correct the errors which further observation has pointed out, and enabled us to discover, and, as it were, purifying the streams at the fountain-head, to secure a purer flow of correct analogy. We naturally look to Professors Grant, Owen, and Jones, from their position and opportunities, for a standard of correct nomenclature which could at once be safely adopted and generally applied; but we are constrained to confess our disappointment in that respect, and more so in the second volume of “Lectures on the Vertebrata,” by Professor Owen, now before us, where his ingenuity seems to have been principally directed to the composition of names from the Greek, which gives the whole a very pedantic appearance. But a still greater fault lies in continuing (without due consideration, perhaps) the antiquated analogies adopted by the older anatomists, which the discoveries and researches of modern observers, under more favourable circumstances, have shown to be erroneous. For what can be more confused and contradictory than the different proposed analogies of the osteology of fishes and reptiles, where, from a careless theory, the pelvic arch and limb has, from its anterior position, been mistaken for the femur, the tibia has been thought to be the scapula, and the tarsus has been forced to furnish the whole of the rest of the brachial limb, while the fibula enjoyed promotion to the rank of a caecoid.

In order to find analogues for the posterior or ulnar extremity, the ventral has been authorized to act their part. As these evidently belong to the endo-skeleton, they can be no part of the endo-skeleton. But the analogies of the humeral zone, with its brachial limb, have been more ridiculous, if possible, whether we adopt the fantastic proposal of St. Hilaire, or of Cuvier and others. An impartial examination of the class of fishes will corroborate the analogies now noticed, and from a conviction strengthened by the last ten years' careful examination, whenever an opportunity occurred, we advisedly denounce as erroneous the whole principle of analogy generally adopted by the best comparative anatomist of the present day. And without entering more minutely at present into all the analogies which may be pointed out, we will proceed to a short review of the work more immediately before us, and shall, from time to time, fill up the sketch of the subject to which we will confine ourselves on the present occasion, namely, that portion of the volume devoted to the osteology of the fish.

Professor Owen has very well described the advantage which professors and scientific students may derive from an extensive study of comparative anatomy, pointing out its application to the investigation and determination of animal existence, both in the present and in former geological epochs. Here he is eminently successful.

Although the whole work has been well got up, as regards its form and illustration, we must still regret that an individual so highly gifted, and so fortunately placed in the rich mine of the Hunterian Museum, and so lately brought within the meridian of royal favour—having been one of the very few who has been in any way substantially rewarded for his devotion to any branch of science in this country, where pigmy monsters and delightful singers seem to be the more favoured nurslings of royal bounty and regard—we repeat our regret that the scientific professor, from a bashful timidity, should have adopted a system of analogy which he found prevalent, lest he should throw the views and labours of the great men who have preceded him in his delightful path into disorder. We pretend to no such mawkish feeling; for, although we will not yield to any one in the respect and

eneration which the names of Hunter, Cuvier, St. Hilaire, &c., are held throughout the whole empire of Science, we hesitate not to point out those errors which further research has shown they had fallen into, and which, we doubt not, they would long ere this have corrected, had the opportunity been afforded them.

At the commencement of the second lecture there is a diagram of a ring, intended to illustrate the analogy or homology of the segments of the exo-skeleton of the articulatæ and the "vertebra" (as Cuvier defines it) of the vertebrata, which St. Hilaire had previously proposed as illustrating the unity of organization.

Examined, in relation to the nervous and vascular central axis, this will be found clear enough; and, if anatomists and naturalists would remember this, we should be relieved of the blunders which place the sternum on the back of insects and crustacea, or of supposing "the position of the brain reversed, and the alimentary canal still intervening in the invertebrate, between the aortic trunk and the neural canal." (Vol. II., p. 22.)

The neural axis or centre is, no doubt, reversed as regards the aspects of the body being found on the lower instead of the upper aspect, as in the vertebrata; but the professor is in error when he states that the alimentary canal intervenes in the invertebrate between the aorta and neural canal.

We feel satisfied that a little review of this statement, with the examination of the organisms themselves, in the vast stores of the Hunterian collection, will convince the learned and scientific professor of his mistake. Had he examined the structures he would have found the suggestion of Scoffern completely borne out in this instance, and would have recollected that the vascular centre is not the aorta, but the heart and vena cava, and that the aorta is merely an important but subordinate branch of the circle; and, although we do not mean to subscribe to all the analogies proposed by this distinguished, though often very fanciful, naturalist, we must support him on the present occasion.

We must remind the professor that his objection to the analogy from the mode of forming the neural canal can at once be removed by tracing the development of the laminae of the perineural arch or canal in the articulatæ animals, where it is connected with their exo-skeleton; while in the vertebrate it rests on the chorda centralis, formed by the bodies of the vertebral column; and if he were to introduce into the diagram a body at the letter E, fig. 5, he would soon appreciate the view of the eminent French savant.

In fact his own fig. 7, strictly studied, would show the true state of the exo-skeleton, enclosing the cartilaginous endo-skeleton:—

an. } Dorsal.
an. } Exo-skel. Sternum (dorsal of the
dp. } entomologists.)
Endo-skel. { Body of vertebra.
e. Body of ver. { Chorda centralis.
n. Neural canal. n. Perineural canal.
pl. Pleurapophysis. pl. Perisplanchnic.
Here, ~~we~~ we suspect the true analogy has been ~~led~~ by adherence to the adopted system the interpretation is completely at variance with the typical vertebra explained in third lecture, to which we now call attention. Here we are again indebted to the suggestions of Geoffroy St. Hilaire, who explained a series of segments in the axis of the body, each one, which he termed vertebra, term possesses rather a wider meaning than it usually does in human anatomy, including the ribs in the region of the chest, and the bones of the face in the region of the head.

IV.

Tested by his own diagram, Professor Owen's analogies are not borne out, as he has noted the hæmapophysis in figs. 6, 7, as pleurapophysis, and states (page 44), "That the pleurapophysis (in the thorax) are much elongated, and the hæmapophysis removed from the cerebrum, and are articulated to the distant end of the pleurapophysis, and the bony hoof being completed by the intercalation of the hæmal spine between the ends of the hæmapophysis." A little observation is only required to show that the whole is the well developed laminae of the perisplanchnic arch or hæmal of Owen. The transverse or pleurapophysis is not indicated. The diagrams of a typical vertebra, agreeing as they do in the general principle, vary somewhat in detail, and we submit II. a as preferable to either of those submitted by Professor Owen, or that more early published by Professor Grant. The one proposed is also in accordance with the language of human anatomy as indicated in II. b. Very considerable advantage will be found to arise in the analysis of the endless variety of form throughout the animal scale, if we adopt a uniform language and definition of the several portions of the typical vertebra. We have long found a great advantage in determining the peculiar character of a lamina (a name familiar to all anatomists), although often appearing under very different forms: sometimes it is found in its elemental form divided into its three parts:—I. Primal, simplex, and orbicular, and, if prolonged, having two convex articulations. II. Dimal, duplex, with two concave articulations. III. Δ Trimal complex; two convex articulations, but generally subdivided into several ranges. At other times the whole is consolidated into a single bone, and even the laminae of the opposite sides are consolidated into one; but still in these cases it is easy to trace the separate elements. There are also to be found laminae which are deficient even in the highest vertebrate animals; it is therefore necessary to form some system for the classification even of a lamina, of which there will be three classes.

I. Vertebral laminae, α , anterior, or superior, or dorsal, β , posterior or inferior-ventral, as found in the perisplanchnic and perisplanchnic arches.

II. Segmental laminae, as in the squama, comati temporal-scapulo-clavicular, or humeral-ileo-pubic, or Coxal.

III. Membral laminae, or the articulated limbs connected with the glenoid and cotyloid cavities, the mandibular or inferior maxilla.

Brachial, or arm.

Complex.

Crural or leg.

With such a system we easily read some of the most complicated organisms we have had the opportunity of examining, and more particularly that of the osseous fishes with which Professor Owen very properly begins. From observing the arrangement and distribution of spinal nerves, it is seen that these correspond with the number of vertebrae in the regions of the back; but, from a misapprehension of the true series of cranial vertebrae, the same law does not seem to apply there; a little further examination will clear away this mistake. The full development of this would lead us too far from the main object we have now taken in hand, and shall, therefore, dismiss it for a future opportunity, and proceed with the osteology. If any progress is to be made in this subject, on sound anatomical data, we fear that the whole interpretation in present use, as well as that more recently proposed and adopted in the work under review must be given up—for we feel confident that it is entirely wrong as regards the osteology of the head of the fish—a conviction forced on us long ago, and confirmed by the experience of a dozen years.

At page 63 there is a diagram with the names of Geoffroy on one side, and those of Owen on the other side, but without indicating the endo-skeleton elements from those of the exo-skeleton. We regret that the osteology of the higher or cartilaginous fishes has been so blended with the descriptive osteology of the osseous, before clear views have been obtained of their simpler inferior. Professor Owen properly points out the error of the distinguished ichthyologist, Agassiz.

Lecture IV. is occupied with the skull of fishes. Professor Goodsir, of Edinburgh, is the anatomist to whom we are indebted for the only accurate description of the lancelet, which will be found published in "The Transactions of the Royal Society of Edinburgh." A work most likely little consulted, which may account for Mr. Owen's passing it so completely over. If we refer to his account, we find that the cranium is not indicated, and that it may be looked on as analogous to the verniform type of invertebrate animals; and that the germ, as it were, of the endo-skeleton appears only in the rudimental form of the *chorda centralis* (not *dorsalis*, as is too generally named)—the dorsal development belonging to the dermoid, or exo-skeleton.

Passing from this verniform type to the osseous fishes more commonly met with, we find the ossification still modified by the invertebrate type. The cutomoid and crustacean type of segmental membral laminae are readily found connected with the cranium of the fish, but still separable from it, if, in our analysis, we adopt the laminar formula above suggested. Overlooking this has misled Geoffroy and others, and the most absurd and fanciful analogies have been put forth, which have prevented the adoption of the views of philosophic anatomists from becoming at all popular with the practical anatomists of the old school—one of whom we once heard declare that Geoffroy was a fanciful madman, and all his speculations arrant nonsense.

This dark cloud of blind prejudice, we feel, is wearing away with the passing and past generations; it is quite waste of time to mould or bend the gnarled and knotted oak, although it may be done with the sapling, especially when the light of science is approaching the brightness of meridian splendour. It is with the rising generation that the correctness of the views of philosophic anatomists are to be made out, and applied to the advancement of knowledge for the use and benefit of mankind.

The data deduced from the observations of Vogt, on the embryo of one of the salmonidae, referred to by Professor Owen, happily indicate the mode of formation of the cranium, and show that anterior to the pituitary sac, it is the cranial; this may be easily traced in the embryo of mammals, and throughout the whole length of the *chorda centralis*, where each vertebra is formed of several pieces.

The pituitary sac (or "hypophysis cerebri," Owen) may be looked on as the centre of the encephaloid region, encircled, as it were, by the ganglionic ring of the asteria, and other types above in the invertebral.

We consider the cartilages developed on each side of the chorda centralis as extending outwards enclosing the internal ear, as forming the petro-parietal lamina, having the sphenoidal part of the basilar process for its body, and not the occipito sphenoidal mass. We are fully convinced that the true analogy will soon point out that, with the exception of the part of the sphenoid first noted, the rest of the bone belongs entirely to the prosencephalon, but that this bone, even in man, is not in a complete state of development, its trimal or spinous process being overtopped by the more expanded development of the frontal and the petroparietal.

ch. Chorda centralis.
hy. Hypophysis pituitaria.
s. Sphenoidal (arches)
—dentata.
16. Acaustic capsula petroparietal.

We must here strongly protest against the application of the term arch to any part of the chorda centralis, which is the homolayer of the column, formed by the bodies of the vertebrae, as the lamina, when united, enclosing the cerebro-spinal axis in the posterior aspect, and the viscera on the anterior, have long been described as arches. We must also regret that a small diagram should be given which does not contain all the parts specified in the text.

We pass over at present the further analysis of the formation of the cranium in the cartilaginous, that we may complete our review of the osseous fishes, within the compass allotted at present by the subject, and also because we have very strong doubts of the propriety of considering the lepidosirantous as a fish. At a future date we may resume this point, which we agree with the professor is of importance.

LECTURE V.—THE SKULL OF OSSEOUS FISHES.

The head of the cod has been very prudently selected for description in this lecture, as, from its size and the ease and frequency with which we meet with it, affords many grounds of preference. The complexities of this cranium, from the great number of bones, will at once subside as soon as we detach those parts which do not belong strictly and anatomically to the cranium of higher vertebrates, and of course homologically are incorrectly described as portions of the cranium. This has tended to obscure the whole analogy, which may be so beautifully traced here, at the same time avoiding the absurdity of supposing the opercular bones as monstrous bones of the ear instead of the arm; and mistaking the corral segment with its cranial motor appendage for the atepular arch.

We hazard our dissent to the homology proposed by the comparative anatomists of the highest merit from our deep-rooted conviction, after careful study and investigation, corroborated by many years' reflection, and also to the opinion, pronounced as authoritative, the work before us.

"The craniology of the head of fishes is more intelligible, more philosophical, and more agreeable with the natural arrangement and true signification of the series of bones of which that complex part of the skeleton is composed, than the craniology of the human skull"—we suppose, for this part of the comparison is not expressed, but it is added,—"In this respect, ichthyology, as a true anatomical science, is at present in advance of anthropotomy." We are thus compelled to add to our mere dissent a most unconditional denial, and further to declare that no true homology will be supported by the animal organic kingdom till the whole subject is reviewed beyond the blaze of the halo surrounding the names of Hunter, Cuvier, and a host of others, who have long illumined our horizon with the brilliance of a meridian sun, and also of those minor lights of science of our present race, who, like the moon, have shed a reflected light pleasing for dreamy speculation, but flickering and false as the phosphorescent luminaries which often deceive wearied travellers when wandering without compass over dangerous moors and morasses.

We esteem highly the authority of Cuvier and Agassiz in many points: in the path of zoogeology they hold the first rank; but it must at once be conceded that neither have a similar position in philosophical anatomy. Cuvier despised analogy as a mere fanciful dream, and sneered at the imaginative theories of his colleague, Geoffroy St. Hilaire. Of Agassiz, as an ichthyologist and ichthyogeologist, we know no one to approach him in a path which he still possesses as his own undisturbed domain; while in the field of analogy and of anatomy he is but an indifferent guide.

We suggest to the talented professor to revise the splendid Hunterian treasures, begared as they have been by the disgraceful destruction of his MSS., for which we know not of terms sufficiently opprobrious to apply to the miscreant who perpetrated the horrid deed: of him we are prevented saying a single word, by the proverb "*de mortuis nil nisi bonum*." He has gone home.

He must also for a time denude himself of his preconceived theories and prejudices, inculcated by the writings of preceding authors, leave to "the packers and makers up" of the goods of others a task which they execute more cleverly than he can, in despite of much experience and labour in this field, and endeavour to manufacture some fabric of his own, and, with a few questions such as we may venture to suggest, proceed impartially to the investigation. We are sure that a short investigation will at once satisfy him of the errors of the existing explanations of comparative anatomy of the fish, and encourage his progress in the right direction, which, with all humility, we submit for his guidance. We are the more anxious to win him from the error of his ways, as a whole host of followers would at once adopt his altered opinion, as affording the materials for a new scizzarsian system, manual, or fresh article in an encyclopedia, or penny magazine for the million. The very pretty works issuing from the London press, illustrating the different branches of science, with the beautiful woodcuts, are an evidence how much can be done to aid the scizzars by the tool of the woodcutter; and the professor of King's College has greatly contributed, by his very beautiful books, to add an interest to comparative anatomy. As he has adopted, without note or comment, Professor Owen's views, we would at once gain him also; and, if not, it is perhaps of less consequence.

Professor Owen arranges the cranial bones of the fish primarily into—

- A. Neuro skeleton.
- B. Splanchno skeleton.
- C. Dermo skeleton.

Overlooking entirely those of the molo-sustentat or locomoto-skeleton, which cannot properly be placed under any of these heads.

Perhaps it may be considered as somewhat premature to enumerate the cranial vertebrae

from the common centre, which we consider to be the sella turcica, the receptacle of the pituitary sac. We think this will happen at no very distant period, as it would certainly be more in accordance with the principles of analogy; at the same time we state no very strong objection to the arrangement here adopted, nor to the names being derived from the primary segments of the brain as a safe principle, although those now proposed do not quite satisfy us. For the reasons already stated, we entirely depart from the distribution of the separate bones as forming the different arches, and especially from classing as hernal arches bones which Spix, Bojanus, and others do not consider as belonging to the head, although they mistake in considering them the arm and shoulder, instead of the iliac and leg. It would detain us too long, and occupy too much space, to notice all the speculations of the system, as we must first get the correction of the principle conceded, and it will be an easy task to work out the detail. There is one part we cannot pass over; the professor is not steady to his own system. He adopts the ergoneous analogy of the pectoral fin of the spine and scale zoologists as that of the shoulder and arm, and describes the bones of the tarsus as the radius and ulna, but in (fig. 40) the case of the *Lepidosteus*, he describes these same bones as those of the tarsus. Had he kept the osteology of the human foot in view he might easily have seen an approach to the resemblance there between the os calcis and navicular as the ulna and radius, which would have prepared him to avoid mistaking the true analogy in the fish's foot, stigmatising it as a certain prototype of the fore limb of other vertebrata.

The speculative portion which occupies the concluding part of this chapter is very pleasing and beautiful, and, in the geological application, deserves our praise; and it is with difficulty we restrain ourselves following out the study; but we must content ourselves with referring on these points to the work itself. There is nothing in the least degree novel in such arrangements, being merely some now change rung on a hackneyed continental peal.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF MEDICINE.

Meeting of June 15; M. BEGIN in the Chair.

CANTHARIDIAN CYSTITIS.

Dr. Morel, in consequence of the communication made to the academy at the last meeting by Professor Bouillaud, on the subject of albuminous urine being found after the application of blisters on the skin, forwarded the principal conclusions of his still unpublished paper.

The action of a blister in the production of cystitis depends neither upon its size, nor upon its neighbourhood to the bladder. The smallest blisters, and those most distant from the vesicae, have produced it in many cases, and the absorption of the cantharides into the system is the cause of the vesical inflammation. As to the preserving power of camphor, it is illusory: that drug does not in any instance prevent the passage of the irritating substance into the absorbents, nor the consequent excitement of the urinary reservoir. The symptoms produced consist in the presence of albumen in the urine, and of false membranes in the bladder, according to the intensity of cystitis. Occasionally, albuminuria is the only symptom: in most cases, perineal pain, spasm of the neck of the bladder, a burning sensation in voiding the urine, may also be observed. As practical consequences, M. Morel points out the possibility of the formation of calculi around albuminous deposits in paralyzed bladders; the frequent mistake in which observers have fallen in attributing to diseases the production of albuminuria, due often to the recent application of a blister. As to the special excitement caused in the organs of generation by cantharides, it is due

to the propagation of the irritation from the bladder to the urethra.

COLD APPLICATIONS ON THE FACE IN SMALLPOX.

M. Tanchon communicated a short paper on the application of linen cloths, imbibed in cold water, to the face, for the purpose of preventing the progress of ulceration, and consequent pitting of the eruption. During the first seven days they should be uninterruptedly applied every hour, and may after that period be gradually ceased. When called after the development of the eruption, M. Tanchon recommends the addition of 5j. of alum or of 3ss. of nitrate of silver to each litre of water.

ELECTION OF A NEW MEMBER.—(Section of Anatomy and Physiology.)—M. Baularger was elected by a majority of 6. M. Manec and M. Desmouilliers each obtained a respectable number of votes.

FARCY.—M. Renault, director of the Veterinary School at Alfort, presented preparations of morbid anatomy, taken from a horse. The animal had died of farcy. The disease had been inoculated with the lancet, and ten hours afterwards the skin was removed in an extent of fifteen square lines, and deep cauterization had been performed, notwithstanding which, general infection and death had taken place.

Meeting adjourned at five.

SECOND VACCINATION.—We read in "The Revue Médico-Chirurgicale" an interesting statistical paper, by Dr. Béringer, on the results of 236 cases of renewed vaccinations. The first class of subjects, 102, were inoculated with virus taken from the arms of infants; in 55 cases the vaccine pustule was fully developed; in 42, fever was present; and in 22 instances the glands of the axilla became enlarged. From these patients the virus was communicated to the second class, composed of 24 persons; 10 only presented a legitimate pustule, and 4, febrile reaction. Sixty-nine persons formed the third class, and received the vaccine matter from the second; the inoculations succeeded only in 21. In the fourth class, 34 persons were comprised, the virus having now arrived at its fourth generation: in eight individuals only was the pustule obtained; and from these eight the virus vaccine was passed, but without any effect whatever, to the fifth class, consisting of ten persons. Hence, Dr. Béringer concludes that, at its fifth generation, vaccine matter seems to lose its power of reproduction.

LIOUIN or SULPHUR IN CUTANEOUS DISEASES.—M. Escobar, physician of the General Hospital at Madrid, has recently studied the physiological and therapeutic effects of this drug; the dose which he recommends for the adult is from two to six grains.—*Clinique de Montpellier.*

ESSENTIAL OIL OF TURPENTINE, EXTERNALLY, IN RHEUMATISM.—M. HÉRIEUX.—When essence of turpentine is poured over a surface, its volatilization is not attended with any pain, or with the production of heat; but, when a compress imbibed in the oil is applied to the skin and covered with a waterproof cloth, the result is far different: violent pain follows in a quarter of an hour, and, doubtless, if the application was prolonged, vesication might ensue. It is this revulsive action of the essence of turpentine that M. Hériveau has endeavoured to produce, and which he has found extremely useful for the purpose of dispelling rheumatic pain. In cases of paralysis due to disease of the spinal cord, muscular weakness and pain were also relieved.

EFFECTS OF ELECTRICITY AND OF STRYCHNIA COMPARED.—The only medical communication of any interest made, at the last meeting of the Academy of Sciences was a paper by Mr. Marshall Hall on this subject. A weak but continuous voltaic current, passing during twenty minutes through the spinal cord of the lumbar nerves of a frog, produces, immediately on removal of the apparatus, a violent tetanoid contraction of the inferior extremities. If, during an interval of time, a frog be placed in a very strong solution of acetate of strychnia, the same

state will be induced. Mr. Marshall Hall, having observed these apparently identical conditions, endeavoured to ascertain if the identity was real, and concluded from experiments related in this paper, that the electrogenic condition is analogous to that produced by diseases in which irritation of the spinal cord is present, and the tetanoid state induced by strychnia comparable to maladies in which irritability of the spinal cord alone exists—such as tetanus, hydrophobia, &c.; in all which reflex action is the principal source of the phenomena observed.

NATURE OF STAPHYLOMA.—Dr. Szokalski, having had several recent opportunities of observing this disease, published in the *Gazette Médicale* the result of his researches. A thin layer from the surface of a staphyloma being examined with the microscope (150 or 200 magnifying power), the texture is found to consist entirely of epithelial cells. The external layer of staphyloma is at first equal in thickness throughout its extent, but, in proportion as the disease becomes more ancient, its thickness increases at the centre, where a sort of nucleus is formed, not the cause, but the result of the transformation. In M. Szokalski's opinion, therefore, staphyloma is not constituted by a disease of the iris, nor by adhesion of that membrane or of the crystalline lens to the posterior aspect of the cornea, but merely by a morbid development of the epithelium of the cornea.

wound, and on the twenty-fifth day the patient was well. Four months afterwards she became pregnant, and was in due time confined of a healthy boy. In December, 1816, she again increased her family, and had another son. 'Thus,' says Dr. Woycikowski, 'disproving the assertion of the Father of Medicine, that male children are generated by the right and female germs by the left ovary.' The right ovary had, in this instance, been removed."

CAUSE OF RAPID DEATH IN CASES OF GANGRENE OF THE SACRUM.—The part which suffers most from dorsal decubitus in fever, says M. Blandin, is that part of the spinal column which corresponds to the union of the sacrum with the os coccygis, and which is protected posteriorly only by a ligament. Gangrene easily, in this region, lays open the canal; hence, air and pus are admitted into the cavity of the arachnoid, and bathe the nerves which constitute the cauda equina: the frequent consequence is, paralysis of the rectum, bladder, and loss of power over the inferior extremities.

D. M'CARTHY, D.M.P.

Sarcina Ventriculi.—Dr. William Basham, in making some clinical observations on the case of a man affected with hypertrophy of the heart, with dilatation, in the latter stage of which there occurred a very irritable state of the stomach, with frequent vomiting, says, that the vomited matter placed under the microscope presented singular cubic and bala-like masses of vegetable development, minutely and regularly marked into sections of quadrupled subdivisions. There were also many tufts of margaric acid, with epithelial cells in abundance. There is much interest in the coincidence of the presence of the sarcina ventriculi in vomited matter of the same physical characters; and it certainly gives force to the opinion of Goodsir, that in special cases the contents of the stomach suffer certain spontaneous or intestine changes, analogous to fermentation, and consequently opposed to the true digestive function, which must for the time be in abeyance; and that, as the consequence of this fermentive process, certain vegetable structures are developed, of which the sarcina ventriculi is an example.

The Relative Value of Microscopical and Chemical Analyses.—Microscopical investigations, says Dr. William Addison, have contributed to the development of a physiological law or order which abnormal changes may be rationally and scientifically tested; whereas, chemical philosophers have done nothing in this respect. Microscopical analysis reveals elements and forms as nearly as possible as they exist in the

living structure—nay, in the living body itself; whereas, a chemical analysis furnishes only the result of complex manipulations, in which unnatural agents are employed, unnatural changes produced, and unnatural products evolved. The materials for the growth and nutrition of living bodies are prepared or elaborated in the interior of closed vesicles or cells, so that when the cell-wall ruptures, and the interior matter is thereby exposed to new agents, new changes occur; and alterations of form and quality, therefore, anticipate a chemical investigation. Vegetable morphology, as a branch of scientific research, owes everything to the microscope, and nothing to the filtering-paper, the test-tube, or the crucible; it is, therefore, reasonable to expect that the normal order of animal morphology may be equally as well illustrated by the same means. Not that microscopical and chemical investigations are to be considered as in any way opposed to each other; on the contrary, the question is—which, in the present state of our knowledge, affords the most useful and trustworthy information? Chemical facts, in their relation to the structure and functions of living beings, appear to me at present, as loose and isolated materials, which may hereafter find their useful applications; but to the microscope will, if I mistake not, belong the credit of enabling us to establish physiological and really practical principles.

Morphological Changes in Consumption.—There is, says the same writer, an increased secretion from the air-tubes; a thickening of the interlobular areolar textures; destruction or thickening of the coats of the blood-vessels; and, finally, adventitious membranes and abnormal secretions on the pleura. If ulceration of the mucous texture of the air-tubes occur, the fibrous texture beneath is thickened and consolidated; and when the secreting texture of the alimentary canal softens and ulcerates, pseudo-fibrous membranes glue the convolutions of the bowel to each other—one texture retrograding into a fluid pus, whilst adjacent ones of a higher type and different order are becoming thicker and more consolidated—serofulous and inflammatory actions running on together, not in the same texture, but in the same organ.

Strangulated Femoral Hernia successfully treated by Opium.—Mr. Charles Mayo related, in the *Provincial Journal*, the case of an old woman, sixty-seven years of age, who became the subject of femoral hernia on the right side about four years ago, at which time it was strangulated, and after some trouble was reduced by the taxis. On the 24th of April last it became strangulated again from some unusual exertion. The swelling was as large as an egg, painful and tender, from her having used much exertion in endeavouring to reduce it. She was constantly sick. A cathartic enema was given, and the taxis used, without effect. Six pills, with a grain of opium in each, were left her, one to be taken every hour. She began at four o'clock P.M., and at nine had taken four pills. After the first the vomiting subsided, and she felt quite easy; cold cloths were kept applied to the swelling, which remained immovable. The fifth pill was taken at midnight, and the sixth at four A.M.; after this she felt completely relaxed all over; her bowels rumbled about, and the swelling seemed to be enlarged and distended with wind; but soon after, on feeling it with her hand, it had become softer, and presently went entirely up under very slight pressure. At six o'clock A.M., a cathartic draught was taken, which operated satisfactorily; and she was delighted to sleep all the day after.—Another case is reported by Dr. Richard Long, of Arthurstown. The patient was a female, forty-seven years of age, with hernia in the right groin, about the size of a large egg, not very painful to the touch, with the abdomen slightly swollen and very tender. There was severe vomiting of a brown coffee-coloured fluid; insatiable thirst; small pulse, 110; cold extremities; anxious and sunken countenance; constipated bowels. She was bled, placed in a warm bath, and a tobacco enema administered,

and the taxis applied, without effect. Pounded ice was ordered to the tumour, an anodyne draught given, and a pill containing half a grain of opium and one grain of calomel to be taken every hour, with an occasional effervescent draught. At noon, next day, her situation was most alarming. The pulse was 120, small and hard; countenance still more sunken and of a leaden hue; vomiting incessant and stercoraceous; abdomen more swollen, and tender; hernial tumour unaltered; occasional hiccough. A tobacco-enema and warm bath were used, and the taxis again tried without success. As the friends would not allow of an operation, opium in large doses was tried. A pill containing three grains of opium and one of calomel was directed to be given every hour, and an enema of strong chicken broth thrown up every fifteen minutes to support her failing strength. The three first pills were speedily rejected; the fourth and fifth were retained; a cessation of pain and vomiting followed, and, by the time that eight pills were given, an urgent desire to evacuate the bowels followed the administration of one of the broth injections, which led to relief and perfect recovery.

Injurious Effects of the Inhalation of Ether.—Dr. James H. Pickford, of Brighton, says that etherization exerts a baneful influence on the blood and respiratory organs. The blood—robbed by ether of its oxygen; impoverished by the solution by the same agent of myriads of corpuscles, of those especially with which it comes into immediate contact; depreciated as a consequence in the quantity, and deteriorated in the quality, of its fibrin; intensely blackened by the solution of its corpuscles and their contained hæmatoglobulin—is chemically deprived to a considerable extent of its powers of coagulation, and rendered unfit for the purposes of life. A black, vitiated blood circulates through the system, analogous in many particulars to that in putrid and malignant fevers. The impaired condition of the blood is not even partially corrected until respiration of atmospheric air has been permitted for some considerable time, and until lymph corpuscles have found their way into the circulation to replace those of the blood destroyed by the ether. In thirty fatal cases, following operations in which ether had been employed in the various hospitals in Dublin, eight were found to be the subjects of recent tubercles of the lungs, the undoubted product, it was believed, of inhalation.

Vulvo-vaginal Gland.—M. Huguier has given a description of a gland situated at each side of the junction of the vulva to the vagina. The gland he describes as about the size and form of an apricot kernel, and is provided with an excretory duct, about seven or eight lines in length, the external aperture of which is situated in the angle between the vulva and the border of the hymen. This gland is small until puberty, when it is developed with the other organs of generation; it becomes turgid during sexual excitement, and secretes a quantity of clear mucus-looking fluid, which it is said to ejaculate with some force. This gland is regarded as closely analogous to Cowper's gland in the male subject, for it is situated in about the same part of the perineum as this latter is; and presents the same anatomical relations and connections. It is an appendage to the vulvo-vaginal cavity, a part which is analogous to the urethra in the male; it receives the materials for its nutrition and its sensation from the same vascular and nervous sources as does Cowper's gland; it presents also many varieties in form, size, and situation; and it may be absent on one or both sides, as is often the case with Cowper's gland.

Testing the Urine for Sugar.—Dr. Rees has pointed out the fact, that the dark colour produced by heating the suspected urine with caustic potash is not satisfactory, unless the purity of the potash be first ascertained. If there be any lead with it, a dark colour will result in boiling the potash and urine, without the presence of saccharine matter in the latter.

Cure of Nerve.—Diefenbach says, in flat nœvi, up to the size of a crown-piece, steeped in

pure liquor plumbi, is to be fastened over the part with a bandage, and wetted by fresh applications of the lead without frequent removal. After days or weeks, the swelling becomes whiter, flatter, and firmer; soon afterwards, little, firm, white spots form on the surface, and the cure is certain. By means of a solution of alum and compression, nœvi, so large that extirpation would have been impossible, have also been cured. It may be necessary to keep the remedy constantly applied for six months.

The Binder after Delivery.—Women in France, after good confinements unattended by any complications, are particularly subject to the passing of large clots of blood, accompanied with severe uterine pains. This is to be accounted for by the French not using a binder after delivery, in ordinary cases; and thus affording practical proofs of the ill effects resulting from the non-application of that useful appendage.

Dry Cauterization of the Cervix Uteri.—The application of the actual cautery, for the treatment of cancer of the neck of the uterus, has been proved to be, by M. Jobert de Lamballe, the least painful, and by far the most effectual, means of treating obstinate, or even what were considered incurable, affections of this organ. He recommends the actual cautery in all obstinate cases of engorgement, or hypertrophy of the cervix, especially when accompanied with induration and deep ulcerations, that have resisted all other means of cure; he has also applied it with marked benefit to cancerous and other malignant growths arising from the same situation, by means of its chocking the profuse hemorrhages which had hitherto been wearing down the patient; and also destroying by its agency the diseased growths so effectually as to give hopes, if applied sufficiently early, that the entire of such diseased structures might be permanently and safely eradicated.

M. Jobert's Cauteries for the Uterus.—He employs three kinds—first, a conical-shaped one; second, one with a flattened extremity; third, the round. The surface of the cautery must be perfectly smooth, and when used should be heated to whiteness. It is to be kept in contact with the cervix uterus one or two seconds, or longer, if you wish to destroy the diseased structure. This mode of cauterization possesses the advantage of rapidity of action; the power of regulating the amount of influence, according to the effect wanted to be produced; it exercises a more decided influence in melting down an hypertrophied cervix than any other application, except the Vienna paste; and destroys more surely malignant disease.

Compression of the Aorta in Uterine Hemorrhage.

—M. Chailly calls this the most precious discovery with which the obstetric art has been enriched. The great nicety in applying the compression is to do so on the aorta alone, without at the same time obliterating the course of the great venous trunk, the difficulty of avoiding which is urged as an insuperable objection against the operation. Chailly does not insist on the pressure being applied higher up than just above the bifurcation of the abdominal aorta into the common ilia; but Negrier says it must be compressed above the origin of the renal arteries, as high up as the umbilicus, so as to command the spermatics, in order to be of any use. One of the advantages particularly dwelt on is the time gained for the patient to recruit: for, according to its advocates, when properly applied, the hemorrhage formerly going on at once ceases, and does not reappear so long as the pressure is sustained. In proof of the efficacy of this treatment, Chailly states that his father practised it once with perfect success, and that he was fortunate enough himself to preserve the lives of several women, who certainly would have perished from frightful losses, only from this method. In one instance he was obliged to continue the pressure for nearly two hours, of which M. P. Dubois was a witness.

Galenism in Narcotic Poisoning.—A woman was brought to the Middlesex Hospital a few weeks since, having swallowed an ounce of

laudanum. The stomach-pump had been used; several pints of water were injected; but during this operation the large quantity of tough, ropy mucus which collected around the pharynx and glottis rendered it doubtful whether she would not die of asphyxia before the stomach was emptied; and the tube of the pump was of necessity withdrawn before the whole of the contents were removed. Pinching, slapping the face, &c., produced but momentary and imperfect consciousness. When put on her legs she immediately fell down like one lifeless. The sponge directors of a galvanic battery were applied, but for the first few minutes no sensible effect was produced; afterwards the muscles of the neck began to quiver, when sensibility gradually returned, and after twenty or thirty minutes the stimulus produced shuddering of the shoulders, and attempts to avoid contact with the sponges; and there was the ejection of a large quantity of fluid from the stomach. In another hour she appeared quite lively, answered questions distinctly, and in a moderately loud tone, though in a peevish manner. When the galvanic current was interrupted for a few moments, she relapsed into insensibility. The pupils remained unaffected for about two hours, when they became somewhat dilated and sensible to a strong light. All the symptoms gradually diminished, but it was absolutely necessary to reapply the galvanic stimulus at longer intervals until half-past five P.M., when she seemed so far recovered as to allow of her removal to the ward. Dipping the sponges of the directors, on this occasion, in moistened salt assisted the passage of the current, and increased the conducting powers to a striking degree.

Precautions to be Employed in Dissections and Post-mortem Examinations.—Dr. Cattell recommends the anointing of the hands with camphorated oil, before handling the viscera; the oil or spirits of turpentine applied to wounds; nitrate of silver; nitric acid; spirits of ammonia; a strong solution of alum; and to old abrasions, adhesive plaster. These are remedies ordinarily adopted, and to these he adds the chloride of antimony; chloride of zinc in a deliquescent or liquid state; creasote; concentrated solution of chloride of soda, or of lime; and, finally, the use of gloves made of vulcanized caoutchouc, which should be kept on finger or hand blocks when not in use.

Muriate of Morphine in Toothache, &c.—M. Ehrhard has always found toothache yield, in from half an hour to two hours, after friction of the gum on the affected side with muriate of morphine, in powder. The first friction should be performed in the evening, at least three hours after the last meal, unless the severity of the pain prohibits delay. It should be repeated in two hours if relief is not obtained; and to be repeated the following day if the pain should return. Half or three quarters of a grain may be employed; but if there should be headache, or disposition to sleep, the friction should not be repeated. When neuralgia occupies the forehead, from a quarter of a grain to a grain of muriate of morphine may be snuffed up the nostril, on the affected side, daily. The mucous membrane to be cleansed by some mollient application.

To Separate Cholesteroline from the Bile.—The bile must be evaporated to dryness, at a gentle heat; then rubbed into powder, and digested for twenty-four hours in a vessel containing a sufficient quantity of ether, shaking frequently during this period. The liquid is then to be filtered and evaporated, and the cholesteroline crystallizes which constitutes the residue to be treated with boiling alcohol. As the alcohol cools, the cholesteroline crystallizes in the form of small white scales, which are rendered more apparent by the addition of water.

Transmission of Ringworm from Animals to Man.—To the few cases which have been published on this subject (by no means numerous) Dr. Ritter, of Rottenburg, adds the following:—A young girl of Wurmlingen, twenty years of age, of strong constitution, engaged in keeping some calves, horses, and a horse, which in

different places had the skin denuded of hair, caught the ringworm, one specimen of which was four inches long and three and a half wide, of the exact figure of *herpes circinatus*, and the itching was so violent as to prevent her obtaining rest either night or day. The internal exhibition of dulcamara and crude anatomy, with the use of an ointment to the part affected composed of white precipitate and hog's lard, speedily effected a cure.

ROYAL MEDICAL AND SURGICAL SOCIETY

J. M. ARNOTT, Esq., F.R.S., President

OBSERVATIONS ON THE COEXISTENCE OF VARIOLA AND SCARLATINA, WITH REMARKS ON THE COEXISTENCE OF OTHER ERUPTIVE FEVERS

By J. F. MASON,

Surgeon to the Smallpox and Vaccination Hospital, London

During the last eleven years, the author of this paper has seen, at the Smallpox and Vaccination Hospital, seven persons who had variola and scarlatina simultaneously. These patients were apparently suffering from smallpox only on their admission, but, in the course of a few days, scarlet fever also developed itself. In each case, all the leading symptoms of scarlatina were well marked, and the eruption was evidently different from the roseola, which frequently precedes the eruption of smallpox, and also different from the erythema (somewhat resembling it) arising from the miasm of hospitals; in fact, it was the ferid red eruption peculiar to scarlatina which no other eruption exactly resembles. Three of the patients were unprotected, and four of them had been vaccinated. All recovered but one, the particulars of whose case were given in full. Three other patients, with variola and scarlatina existing at the same time, have been seen, within the last few years, at the London Fever Hospital. Reference was made to the opinion so strongly expressed by Mr Hunter, that no two fevers could be coexistent. Several cases were then alluded to, that have been published by different observers, in France and England, of the coexistence of variola and scarlatina, variola and rubeola, variola and pertussis, variola and vaccinia, rubeola and scarlatina, rubeola and vaccinia, rubeola and pertussis, variella and vaccinia, pertussis and vaccinia. The individuality of erysipelas, as a special eruptive fever, was commented on, this disease being shown to arise, almost invariably in hospitals, from the impure air produced by morbid animal effluvia. The French were acquainted with the fact, fifty years ago, of smallpox and scarlatina existing together occasionally, some cases being referred to by the author, published by M. G. Vieussens, at that period, but the subject has nearly escaped attention, or at least, remark, by writers of this country.

REPORT OF SOME CASES OF MOLLUSCUM CONTAGIOSUM, WITH REMARKS ON ITS HISTORY AND PATHOLOGY

By Richard Payne Cotton, M.D.,

Member of the Royal College of Physicians, London

The author commenced by a description of the disease, as lately seen by him in a respectable family, in which the mother and three daughters were affected, and the father and two sons exempt. It first attacked the eldest girl, and subsequently all the female members of the family, commencing in the form of prominent, rounded, movable tumours, smaller than a pin's head, which after a few months increased to the size of a large pea, and through it presented a small central depression reminding that of a smallpox pustule, they were red, soft, and painless, but in the process of growth became hard and warty, their attachment was often lobulated, but more commonly by a broad base. No inconvenience attended them unless they were exposed to friction, and the surrounding skin was never inflamed, they were usually arranged in groups, but never coalesced. At first,

an opaque, creamy looking, inodorous matter escaped from the central depression upon pressure, but as the tumours grew this secretion became indurated.

A drawing of the microscopical appearances of the secretion was exhibited, by which it appeared to be made of two distinct structures, one cellular, the other fibrous—the former composed of elliptical or spherical cells, the latter, of wavy fibrils resembling the white fibrous element. From the central depression being formed by the contracted opening of a duct, the absence of the tumours upon the palms of the hands and soles of the feet, where sebaceous glands do not exist, and the lobulated form of the hard secretion, the author concluded that these organs were the seat of the disease. An account of the microscopical appearances of the contents of comedones, or retained sebaceous matter, was then given, and shown to be dissimilar to that of molluscum. The origin of the disease in the cases reported was referred to some peculiarity of organism inherited from the mother, and not to contagion. The rarity of the affection was then spoken of and reference made to cases already described by Bateman, Cazenave, Thomas Wilson, and Drs Henderson and Pateron, from which it was inferred that some were really propagated by contagion, whilst others seemed incapable of becoming so, that the secretion in some cases was simply sebaceous matter, but in others a peculiar and independent organism. Hence, it was concluded by the author that the disease is contagious or not according to the nature of the secretion, its seat remaining the same. That Bateman's division into molluscum contagiosum and molluscum non contagiosum would therefore be insufficient, as he had applied the latter term to an infection distinct from the one described in the report, and not spoken of by subsequent authors, but probably some molluscular tumour, and it was proposed to limit the term to the disease hitherto called molluscum contagiosum. The affection terminated either by an escape of the secretion, which was rare, or its induration, and the formation of a permanent warty tumour. The treatment consisted merely in removing the tumours, and checking the tendency to their development by friction of the skin and ablations, the general health being remarkably good. As soon as the tumours appeared, pressing out the secretion, and the subsequent application of nitrate of silver produced a speedy cure, but, for those more advanced, three methods were adopted: 1, removal by scissors; 2, ligature; 3, the evacuation of the secretion through a small puncture, followed by the application of nitrate of silver. The last treatment was the most successful.

CASE OF VARIATION OF THE HEART, IN WHICH DEATH RESULTED FROM OBSTRUCTION OF THE TRUNK OF THE PULMONARY ARTERY

By Thomas B. Pearce, M.D.

The subject of this case was a boy, fifteen years of age, who had from early life exhibited slight appearances of cyanosis. Twelve months before his death he was thrown from a cart, and after that period the lividity of the countenance became much more marked, and he was subject to frequent attacks of chest affection, and to palpitation. His last illness was of eight days' duration, and commenced with rheumatic symptoms, followed by difficulty of breathing and pain in the chest. When admitted into the Royal Free Hospital he exhibited very marked cyanosis and a loud murmur, accompanying the impulse of the heart, was audible in the præcordia and along the sternum. At the expiration of the first of the heart the murmur marked all other sounds, but towards the apex, and the lower and right side of the sternum, it was followed by a loud second sound. He died a few hours after his admission. On examination, the aorta was found to arise in part from the right ventricle, and the orifice and trunk of the pulmonary artery were very small size. The right ventricle was also separated by a supernumerary septum into two cavities, one being the infundibular portion, giving origin to the trunk of the

pulmonary artery; the other consisting of the sinus of the ventricle, communicating with the aorta. The abnormal septum was incomplete over a space about equal in size to that by which the aorta communicated with the right ventricle. The orifice of the pulmonary artery was provided with only two valves, and those were so thick and rigid as to occasion a further contraction of the aperture. The trunk of the vessel was entirely obstructed by partially decolorized coagula, which were laminated and adherent to the thickened and diseased valves and coats of the vessel. The author remarked that the case was closely allied to the ordinary form of malformation, in which, with congenital contraction of the pulmonary artery, the septum of the ventricle is defective at the base, so as to allow the aorta to receive its supply of blood from both ventricles. Its great interest, however, lay in the division of the right ventricle into two cavities communicating with the aorta and pulmonary artery respectively, and the free admixture of the venous and arterial currents of blood, which must consequently have taken place throughout the whole of the boy's life. So far, however, from this having been productive of marked cyanosis, it was stated that there was but little peculiarity in the boy's appearance till the supervention of secondary disease in the pulmonary artery after the full, twelve months before his death. The cause of death was also, it was remarked, unusual. Though obstructions in the terminal branches of the pulmonary artery had been shown by Brown and Paget to be of frequent occurrence, the writer was not aware of any other case in which the trunk of that vessel had become obstructed.

ON TUBICULAR HARRIATION OF THE BONE, CONSEQUENT UPON GOUT

By Alexander Ure, Esq.,

Fellow of the Royal College of Surgeons, and Surgeon to the Westminster General Dispensary

The author observed that, upon making a transverse section of a distal phalanx, taken from a gouty subject, peculiar speckled appearance was perceptible. The medullary canals were seen preternaturally enlarged, and filled with a calcareous matter, which effervesced with acids. The Haversian canals were, in like manner, irregularly enlarged and choked up with the substance. The osseous lacunæ or corpuscles were, in some places, increased in size, and rounder than ordinary, but, for the most part, less distinctly marked. The canaliculi, more especially in the vicinity of the medullary canals, were complete with the above deposit, thicker than normal, and in obvious communication with the medullary canals. There was thus induced porous evaporation of the bone. The author stated that the matter in question consisted chiefly of carbonate of lime, while a portion of tophus, detached from the adjacent phalangeal joint, was almost wholly composed of urate of soda. In reference to the above peculiar condition of the osseous structure, he remarked, that Dr Gaillach, of Mayence, whose operation he had in the above instance, subsequently ascertained that precisely the same appearances were present in the section of bone taken from a person who had been afflicted with morbus coxæ senilis. Arthritic osteoporosis is an affection of a very insidious character. It commences almost imperceptibly, creeps on stealthily year by year, and is accompanied by occasional pain and swelling. Although usually occurring in individuals but dimly predisposed to gout, it is not necessarily preceded by a fit of that malady. While the author believes it to be but little amenable to treatment, he is of opinion its progress may be somewhat retarded by judicious hygienic measures; and the attendant pain and uneasiness relieved by topical steam-baths, in conjunction with the vapour of mineral naphtha, and by various other soothing means.

OFFICE OF ORDINANCE, June 16.—Ordinance Medical Department.—Henry Fisher, gent., to be Assist.-Surg.

REVIEWS.

Observations on the History and Treatment of Dysentery, and its Combinations. By WILLIAM HARTY, M.D. Second Edition. 8vo. Dublin: 1847. (Pp. 303.)

The first edition of this work appeared more than forty years ago, and was favourably received by the professional critics of that day. During the subsequent years of his practice, Dr. Harty has continued to devote much of his time and attention to the subject of dysentery, in its simple and complicated forms; and the issue of this long and arduous labour is the volume before us. The work throughout bears a twofold tribute to the author's judgment as a physician, and capabilities as a scholar. In almost every page is the evidence of the practical man, in the simple, unpretending enunciation of the direct truths which are only to be gained at the bedside or in the dead-house; whilst giving a variety and richness to all this, is an elegant and copious selection from the best authors, both ancient and modern, on the several subjects where corroborative or contrasted opinions may be desirable.

Concerning the affinity between dysentery and rheumatism—an affinity stoutly denied by some, and by others, ourselves in the number, admitted often to exist—Dr. Harty speaks in the affirmative. He thinks that rheumatic inflammation, contrary to the phlegmonous, is "seated not so much in the arteries as in their exhalent extremities, which, when inflamed, pour out greater quantity of their contents than the absorbents can take up within the same time thereby inducing both pain and swelling. From this peculiarity in the seat of rheumatism, and the character of the temperaments most subject to the disease, it appears that in this affection, nor other evacuations, that of the skin alone excepted, are equally advantageous or necessary in this as in phlegmonous inflammation. The peculiarity in the seat of rheumatism may suggest some reason why we never find a purulent secretion consequent on the disease, and why the red flush of inflammation is so rarely observed on the parts affected by it." (Pp. 31, 32.)

The cause of dysentery he refers "to an inflammatory action in the innumerable exhalent vessels on the mucous coat of the intestines, similar to that which takes place in serous membranes when affected with rheumatism. Under this state of the vessels, the quantity of their secreted fluid is considerably increased, and its quality, perhaps, somewhat affected: the intestines by this stimulus are excited to spasmodic constriction; and, from both these circumstances united, all the other symptoms may be deduced: hence we have frequent stools, with coexisting constipation; hence we have tormina, with tenesmus." (Pp. 37, 38.)

Concerning the contagiousness of dysentery, which is quite a *questio vocata* with pathologists, Dr. Harty inclines to the belief that the disease is not contagious *per se*, but only when complicated with typhus fever.

"We have seen that the disease is held by the best authorities to be, if not always, at least very often, contagious: and as we have shown that it is devoid of this property, both in its simple state and in combination with intermittent and remittent fever, so we must necessarily infer that the combination with typhus fever alone can constitute the contagious form of the disease." (P. 118.)

"Dysentery, therefore, can no longer be deemed a contagious disease in itself, though capable of acquiring that property under peculiar circumstances. Thus, we see that a contagious disease can so intimately associate itself with another, not possessed of that power, as to communicate both diseases, and not that merely which was in itself contagious." (P. 143.)

Still this does not, in our opinion, prove the contagiousness of dysentery *per se*. There can be no doubt whatever, that in its uncomplicated forms this disease is not communicable. There is

only one malady with which it is ever allied, showing proof of contagiousness as a twofold disease: that malady is typhus. But dysentery does not exist with typhus as an ally; when the two go together, the former is generally only a symptom of the latter, or a pathological state arising out of it. Genuine typhus is never free from more or less disturbance in the mucous membrane of the bowels. Sometimes it is in the small ones, and we find congestion, inflammation, and ulceration there; sometimes it is in the rectum, and what superiorly would be tormina is here tenesmus. These cases of typhus may propagate themselves, and in some instances the communicated disease will be attended with special suffering in the lesser bowels, and in other instances in the larger. But we should surely not say that the inflammation or ulceration of the jejunum or ileum was contagious; and we see no reason for affirming the same thing of like affections of the rectum. The fact is, it is the typhus which is communicated; and the dysentery may or may not come as its consequence.

On the treatment of dysentery our author is very explicit, ample, and essentially practical. His observations and suggestions, derived from experience, are very clear on the use of evacuations, tonics, sedatives, and counter irritants, in his troublesome disease. In the several divisions of treatment, he recommends the judicious use of venesection, emetics, purgatives, diaphoretics, warm bath, swathing, and mercury; bark, wine, and other cordials, opium and tobacco; blisters and turpentine, according as the circumstances of each particular case may call for one or other of these remedial agents.

The work is written in a very lucid style, except that there are occasionally long Latin quotations and epithets, which would have been as well translated or left out. Altogether, the volume does its author the greatest credit, and we gladly add this testimony in its favour.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any News or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein, Carfax, or an order on some party in town, the Guinea IV IN ADVANCE, which will fire them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

A Subscriber, Boston.—Question 1. Christians, or Guy's. 2. See Astley Cooper's.

L. A. C., Clekenwell.—Admission may be obtained by application at Apothecaries' Hall. The gardens afford excellent specimens of some very rare plants, and in the examination for the certificate fresh specimens of plants mentioned in the Pharmacopœia are often brought under the notice of candidates, to test their knowledge of medical botany.

A Young Surgeon, Cheltenham.—A library can never be called complete, however extensive the collection of books. It would occupy too much of our space to enumerate all the columns which ought to be found in the library of a medical practitioner.

One about to settle. We can offer no opinion, as we have no knowledge of the parties. Consult one respectable medical agent, or advertise in the columns of the Medical Times.

Mr. James Hinton.—The certificates are not exactly in accordance with the requirements of the Hall and College. The required information may be obtained by addressing the secretaries.

B. B.—The parties are liable to a prosecution; and, as they are ignorant and impudent quacks, their career ought to be immediately checked.

A Correspondent, Rochford, Essex, informs us, "that a man, with whom he was acquainted, admitted into the London Hospital about months ago, with a compound fracture, and amputation was performed below the knee, while the patient was under the influence of ether. He died about a month after, though the note of good health, and was very temperate. Had he either done anything to do with the fatal result?" It is impossible to say, without further information.

A Member of the College.—Professor Owen delivered a course of lectures on the Anatomy of the College of Surgeons, last.

A Medical Traveller.—We have not seen any medical journal in modern Greek has been published at Athens.

A Student of the Royal Infirmary, Glasgow.—The case presents many points of interest, but, as a similar one has been very recently published in our columns, we must, therefore, decline our correspondents' offer. He has our thanks for the communication.

Medico-Chirurgus, Aspetria.—Ques. 1. The apprenticeship is indispensable. 2. King's College Hospital. 3. There is no chance of obtaining the appointment without personal application.

Medicus.—We did not publish the case, because it was not sufficiently authenticated. The name is not in the Directory.

A. E. Collyer.—The lectures will appear nearly every week till they are completed. Our correspondent is thanked for his offer, which is accepted.

An Assistant, Brompton.—The fee is the guinea, without a post-mortem examination. The medical gentleman who attended ought certainly to have been consulted.

A. M.—Special certificates would certainly be necessary. Consult the Medical Times Almanac.

Mr. Edward Simpson.—The subject will be taken up by us in an early number. The communication shall appear.

O. P.—It is not necessary now to publish the letter, as the rickety bantling has departed this life, after a very brief and chequered existence. Requiescat in pace!

A Reformer, Westham.—The communication has been recently pruned under the influence of fear.

A Firm Friend of the National Institute.—The number who have withdrawn are very few. Our correspondent informs us "he has heard that some of the principal enemies of the general practitioners have been seized by Giant Despair, and are now locked up in Donning Castle."

A Medical student, Bow.—The case of strychnine, occurring in the practice of M. Arland, surgeon to the French navy, was published in one of the March numbers of 1846.

A Country Accoucheur.—Galvanism has been applied successfully in uterine hemorrhage both before and after delivery; but it is a remedy which cannot be generally used in country practice. If he will send us the case in which he administered the agent with such singular results, it shall be published.

Anti-Humbler.—The letter is severe, and under present circumstances it would be useless to insert it.

Dr. Thomas Clissold.—A private communication has been sent.

Philos-Chirurgus is evidently very warm and enthusiastic in his profession. He must remember, however, that in the pursuit of knowledge many difficulties have to be encountered, and that success does not always accompany merit.

J. E. L., Bedford.—The French Medical Bill has not yet passed into a law.

Mr. J. E. Lander, Shiffnal.—It is usual for one medical gentleman to assist another in case of need without any charge, unless they are not on friendly terms.

Mr. John Dale's letter to Sir James Graham and to Vox Veritatis received.

Chirurgus, London.—The Apothecaries' Company has the power of prosecuting illegal practitioners. It is both "necessary and advisable to pass the Bill."

George Ross, Esq., 4, Hanover-square.—The copy of the constitution and by-laws of the National Institute was received too late for insertion.

Mr. R. H. Powell, Rock-lodge, Tunbridge-wells.—The communication has been received.

Prætor.—Any of the numerous officers which advertise on the cover of the Medical Times will endorse the children, under certain regulations.

Mr. J. P. Heane, 8, Barton-street, Gloucester.—The lectures of Dr. Keen will be commenced within a short time.

We shall next week publish the laws and regulations of the National Institute in the form they are to be submitted to a general meeting.

Our friend H.'s wit on the "dishonoured bill"—the registration measure—is admirable, but we fear we can find no space for it.

A Pupil.—Apply to Mr. Balfour, of the College of Surgeons.

Erratum.—We are informed that the reference in our columns last week to the Gazette, as dead, is not literally true. We are always happy to correct obituary notices, especially of a contemporary.

Mr. Johnson is mistaken in his critique. The author is right, and our correspondent wrong.

A Pupil, who writes to us on the London Hospital, should have sent his name.

Mr. W. F. will oblige us by sending us the order of the coroner. There is no doubt he was at fault.

Will Beta authenticate his note? The circumstances of the hospital would appear to require a change, even for its continued existence.

We have received several more letters about Dr. Ryots' entry in "The Provincial Directory." All the facts are none, however, before the public, and are now of too little public importance to require or justify further commentary on either side.

Letters and communications have been received from Mr. James Hinton; Dr. Thomas Chasold; J. L. E., Bedford; Philo-Chirurgus; Anti-Humbus; A Country Accoucheur; A Medical Student, Borough; A Firm Friend of the National Institute; A Reformer, Westham; O. P.; Mr. Edward Simpson; A. M.; An Assistant, Brompton; A. B. Collyer; Medicus; Medico-Chirurgus, Aspatris; A Student of the Royal Infirmary, Glasgow; A Medical Traveller; A Member of the College; A Subscriber, Boston; L. A. C., Clerkenwell; A Young Surgeon, Cheltenham; One about to Settle; B. B.; Mr. E. Lander, Shiffnal; Mr. J. P. Heane, Barton-street, Gloucester; Prater; Mr. R. H. Powell, Rock-lodge, Tunbridge-wells; G. Ross, Esq., 4, Hanover-square; Chirurgus, London; Mr. John Dale, Yarm, Yorkshire; Mr. T. Haynes, Thirsk.

Subscribers wishing to complete their sets for binding are recommended to do so at an early period, as it is not intended to repeat any reprint of back numbers.

THE MEDICAL TIMES.

SATURDAY, JUNE 26, 1847.

THE ILL-FATED MEASURE.

There can be no division of our profession not resigned under the decree of the Medical Registration Bill. The thing was not an honour to us in whatever aspect considered, from that of morals down to that of history. It was, to say as little as possible, not original, nor comprehensive, nor statesmanlike, nor safe. If a measure for which we could be fairly considered responsible, it must have lowered us ninety per cent. in popular and parliamentary estimation. Fortunate for us, the profession very significantly washed its hands of the responsibility; and even the author must, by this time, be glad, as we are, that he has seen the last of it.

Passing by a sad retrospect of defunct or adverse Associations, we cannot forget that this is that gentleman's second year of bill discomfitures. The treatment he helped to mete out to Warburton, Hawkland and Graham (to omit others) has at length been mowed out, in increase, to him.

Will he, then, with this broad hint to oblige us and the profession by no intruding on us his, possibly, well-meant but repelled labours? Will he kindly

save THE MEDICAL TIMES the necessity of again recurring to the subject of himself and deplorable activity? He could do us no higher favour, and—if that be a poor appeal to his generosity—can do himself no greater service. It is the price—surely not a high one—at which he will secure pleased and grateful silence from us, and plenary condonation from the profession. His medical legislation has not succeeded with him the last five years—nor will it the next: and we are quite sure the truce we offer him would as much serve his interest as the profession's liking. Will he accept it? He should: for he may be assured that, like Wolsey, there would be no phase in his medico-political life more becoming than his "leaving on it."

Believing that this result would be one of the most practical services our profession could receive, we shall not stand in its way by the indulgence—however tempting—of a very natural feeling of triumph and exultation. We will this week, therefore, give the deceased bill all the honours of dead humanity—and, as we cannot praise, be silent. *De mortuis nil nisi bonum.*

PERILS OF THE PROFESSION.—THE CORONER'S INQUEST AT HERTFORD.

THE character of a medical practitioner is all that is valuable to him, for upon its integrity depends his usefulness and prosperity. In no profession is it more necessary, and in none is it so exposed to injury and destruction. The benevolent acts of a medical gentleman may be turned to his own disadvantage, and the judicious exercise of talent may be misconstrued into the grossest ignorance. While in other callings character may be sometimes roughly handled, without any permanently serious consequences, in the medical profession it assumes such a delicate constitution that the smallest amount of rudeness towards it may be followed with fatal results. It is no strange thing to see men in the height of prosperity cast down into the depths of obscurity and contempt by the publication of an unjust suspicion. Professional reputation is, therefore, a thing which ought to be so highly valued as to make us very watchful for its safety, and to countenance no proceeding which is calculated in the least to affect it.

These remarks have been suggested in consequence of an inquest which was recently held at Hertford, to inquire into the cause of the death of a man named George Jeffreys, a detailed account of which is given in another part of this journal. The man had been addicted to drinking, and had lived in a state of concubinage with the woman who figured as principal witness at the investigation. He was attended by Mr. Reilly in his last illness; and a day or two before his death, after taking a dose of his medicine, he exclaimed that the "stuff would kill him." He did continue to get worse, retaining the impression to the last that the medicine "had done for him." This wild expressions of a dying man are—strangely enough—made the basis of a judicial investigation, and the coroner, without waiting for the parish authorities to summon him to duty, establishes his court and takes the deposition of the witnesses. The point sought to be established was, that the "stuff" which the patient had taken contained some deleterious ingredient, and the accusers retained the bottle in their possession till it was delivered to the constable.

Dr. J. Davies performed a *post-mortem* examination of the body, and found sufficient cause

of death in the liver—preternaturally enlarged, "of a very dark, black, dirty colour, and in what is vulgarly called a rotten state." The stomach presented no very remarkable appearance, and, upon the application of a few tests to the medicine, it was found to consist of solution of acetate of ammonia, coloured with the compound tincture of lavender.

Such an investigation must have been a source of great pain to the medical attendant, though fully conscious of his own integrity; and, while the results are completely favourable to his skill and beneficence, it is another proof among many of the dangerous position in which medical men are placed when prosecuting their professional engagements.

The sick man, in the pangs of dissolution, had the impression that this medicine was the cause of all his suffering, and it is not quite clear that certain parties did not urge the friends of the deceased to insist upon an official investigation, merely to annoy the professional attendant. If this were the case, they have signally and deservedly failed.

The practice of medicine is indeed beset with many dangers, the surgeon being oftentimes expected to effect a cure when the case is hopeless; and the death of the patient is viewed not as the inevitable result of disease, but of the doctor's want of skill. Even his pills and draughts are too frequently blamed for inflicting the very sufferings which they were intended to mitigate, and the consequence is, that by the diligent propagation of unjust insinuations, his prospects of success are for ever blighted. Neither must it be forgotten that medicine has been sometimes made the vehicle of administering poison to an individual in order to destroy his life. Judge Alderson relates a case to this effect:—A medical man prepared some medicine, into which another put a poisonous ingredient, in order to destroy the person for whom the draught was intended. The patient not liking its taste, and thinking there was something suspicious about it, sent it back to the compounder, who, knowing of what drugs he had composed it, and wishing to prove to his patient that he had done nothing wrong, drank it himself, and died.

Add to these injustices that it is not an uncommon thing for the poorer classes of people to endeavour to free themselves from the obligation of discharging a debt due to the surgeon by reflecting upon his skill, thus inflicting a double injury, by robbing him of his right and wounding his reputation. This is, doubtless, one of the reasons why medical men are so seldom found urging the payment of a bill by proceedings in a court of law.

The testimony of Dr. Davies was creditable to him, in not only exonerating the medical gentleman who attended the patient from all blame, but in declaring that he considered, from the evidence adduced and the manner in which the proceedings were instituted, that Mr. Reilly had not been well used.

The conduct of the coroner appears not altogether free from blame, in so hastily placing a medical man, if not exactly in the position of a culprit, in one very nearly akin, for he was suspected of having given his patient improper medicine; and the fiat of the jury was to decide the matter. It is high time these magistrates were taught to exercise their authority with a little more discretion, that the members of the medical profession may not be subjected to those annoyances of which they so justly and so frequently complain.

THOMAS WAKLEY, ESQ., VERSUS HIS OWN REGISTRATION BILL.

(From a Correspondent.)

THE general practitioners have only to appeal to Mr. WAKLEY for an honest opinion on his Registration Bill. The bill proposes to repeal the penal clause of the Apothecaries' Act; and Mr. Wakley has emphatically addressed the general practitioners in the following words:—

"The announcement of the meditated REPEAL OF THE ACT OF THE APOTHECARIES,—the announcement of the intended ANNIHILATION of that basis on which alone stand the decisions of the Judges of the superior courts, making it unlawful and penal for chemists and druggists, and all other unqualified persons, to practise medicine in England and Wales,—that announcement, we say, has struck upon the ears of general practitioners with a startling, a stunning effect; and is, happily, arousing them not only to a true sense of the danger of their present position, and to a clear foresight of the injury intended for them, but it is also producing in them a fixed resolution to engage in a just and holy struggle for the maintenance of their own honourable professional character, and for increasing the amount of their utility amongst their fellow-citizens."

Mr. THOMAS WAKLEY proceeds:—"Whilst the general practitioners of England and Wales cling to the Apothecaries' Act—supporting as it does the decisions of the Judges—as the only existing check and barrier against their being swamped by an overwhelming tide of unlawful practice, the graduates in medicine of the universities and medical colleges of Scotland and Ireland are at this moment actively memorializing the Government and petitioning the Legislature for the UNQUALIFIED REPEAL OF THE UNCONDITIONAL DEMOLITION OF THAT STATUTE."

This was the language of Mr. Thomas Wakley in the month of March, 1844. (Leading article of the "Lancet," March 9th, p. 794.) On the second day of the same month, in a leading article also, he furnishes his readers with his own estimate of the value to the general practitioners of the penal clause of the Apothecaries' Act, in repressing the practice of the chemists and druggists especially; he states that, with the repeal of that act, will be annihilate "the vitally important decisions of the Judges of the Court of Queen's Bench, interdicting the medical practice of chemists and druggists."

But Mr. Thomas Wakley was at that time engaged in organizing "THE MEDICAL PROTECTION ASSEMBLY," and "annihilating" the MEDICAL TIMES—at which, by the way, both attempts proved only his wretched imbecility. This respectable, consistent, and redoubtable individual is now the author of the "Medical Registration Bill," which proposes to repeal the penal clause of the Apothecaries' Act, and thus "to annihilate the vitally important decisions of the Judges of the Court of Queen's Bench." The insulted general practitioners have only to appeal from Mr. Thomas Wakley, the author of the bill, to Mr. Thomas Wakley, the editor of the *Lancet*, and those who have been his foolish dupes must treat him with the well-merited scorn which such contemptible conduct has so richly earned.

The words in small capitals are exactly as printed in the *Lancet*.

ADDRESS OF MR. SKEY.

TO THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

GENTLEMEN,—A recent circular of the college will have apprized you of my relation to the council of that institution. The circumstances which have afforded me this disagreeable notoriety are peculiar, and, inasmuch as they point to my possible exclusion from the council for ever, I trust I may stand acquitted of indecency, if I intrude my name once more on your attention.

My tale is fortunately short, and is not without its lesson to succeeding aspirants to the honour of a seat at the college council board.

At the nomination of 1846, I was informed that my name would be announced for election. It was so announced. It passed, however, unnoticed, and my junior was elected. I owe my non-election to a morbid opinion I entertain, that every office of public trust, like that to which I thought it not improbable I was about to be appointed, should come by right, and not by favour. Having no personal inclination to gratify, which might warrant a personal obligation, I felt that it would derogate from my honour, and from my independence, if I made a private application, even to a friend, the path to success. However willing I may have felt to undertake the duties and responsibilities of the council, I did not estimate the value of my services so highly as to warrant my adoption of indirect means in obtaining a seat at its board. I consider a personal canvass, or an application in any form, indirect means, and I declined to adopt them. My present opinions and my future intentions, notwithstanding the experience of the past, remain to this hour unchanged; and with such opinions, be they right or wrong, I will not compromise myself so far as to accept an office which demands the advocacy of public and often contending interests, and by the instrumentality of private favour. I do not conceal the fact of my disappointment in the result, but I have never reproached myself for my failure.

Many of my personal and intimate friends were present on the occasion in question. That they reproached themselves for my exclusion, I am quite content to know: one and all endeavoured to acquit themselves by the assurance that "I had no one to blame but myself;" but, as I do not blame them, I do not see why the charge of failure should necessarily recoil on myself. It is a source of great satisfaction to me, to acknowledge that any regret I felt at my possibly temporary exclusion was more than compensated by the kind interest expressed to me personally, by the almost entire body of the council, at an event which was apparently the result of accident merely.

On the 1st of July, a vacancy will be declared by the necessary retirement of three gentlemen from the council board.

Let it not be supposed that I aspire to fill either of the three offices thus vacated, notwithstanding the announcement of my name in the college circular, as eligible for the office. These three gentlemen, with high professional rank and the experience of two years of the duties of the office, will be re-elected as a matter of course. Should, however, either of the three fail of re-election, my name will be proposed, and, if unsuccessfully, I am informed that, in obedience to the requisitions of the college charter, I shall be excluded from the council for ever. This negative position I am not ambitious to fill. While I would shrink from obtruding myself either on the council, or on the notice of the Fellows at large, I do not pretend indifference to the honour of a seat at the council board of the College of Surgeons of England.

I am, gentlemen, your most obedient servant,
H. S.

THE EDUCATION OF IDIOTS.

[To the Editor of the Medical Times.]

SIR,—Can anything be done to ameliorate the physical and moral condition of this unfortunate class of the human race? Are there existing any institutions where efforts are made to improve the habits of children born with defective intellect; of congenital idiots, whose mental organization is of the lowest grade? It is a fact that such institutions do exist on the Continent, and the most happy results have followed the use of means to raise these objects of our pity to a position useful in the sphere they occupy, and the attainment of qualities which have rendered

their social condition a source of gratification. In this country, however long fought for the support and extensiveness of philanthropic and benevolent institutions, not one is to be found for the reception of the imbecile, with a view to the cultivation and training of his low and imperfect mind, for the improvement of his moral habits, and qualification for those practical duties which prepare for the useful sphere of life. The deaf and dumb are regarded as objects of sympathy and compassion, and their interests have called forth the full tide of benevolent exertions in their favour, while it is a fact, that juvenile idiots have been neglected and left to their fate, without a solitary effort being put forth to ameliorate their condition, and raise them from a state of degradation all but on a level with the animal creation. Why, may we ask, is it that the philanthropy of the Continent should be in advance of the benevolence of this country in this particular? Why has France and Prussia deemed it important to stretch forth the hand of pity, and so nobly and disinterestedly come to the aid of this unfortunate class of beings, whose claims on their sympathy have met with so generous a response? Let England answer the question by the resolve, never to rest until she has imitated their example, and raised an institution worthy of her great name for the reception of juvenile idiots, their training and improvement and moral cultivation, until they shall rise into manhood, better qualified to occupy the station allotted them by Providence, instead of dragging out a miserable and wretched existence. The records of the Bicêtre establishment in France, and of the Berlin Deaf and Dumb Institution, place beyond a doubt the favourable results of the skilful treatment adopted to ameliorate the moral and physical condition of this class of individuals. A German newspaper contains the following:—"The instruction of idiots has succeeded; the problem, theoretically and practically, has been solved by M. Sargent, in conjunction with M. Sacks, first teacher of the Deaf and Dumb Institution, Berlin. So fully assured are the Prussian Government of the complete efficacy of the system, that a portion of the Deaf and Dumb Institution at Berlin is to be set apart as an hospital for idiots, where the most effective methods of education can be tested and carried out. All were imbeciles intrusted to the care of M. Sargent: they were twelve in number. After the lapse of some months, those who could hear were learning to speak; some were beginning to draw and write, and some to sew; others played most naturally, and sang and danced as other people; all appeared neat and cheerful, improved both in mind and body. A deaf boy, who was one of the worst cases, washed and dressed himself daily without assistance, and was learning to draw; he made his picture upon a slate, and evinced quite a passion for the employment. Most of them appeared in a hopeful way to attain ultimate restoration to the rank and society of rational beings. M. Seguin (of Paris) was also intrusted with the care of ten idiots, who were inmates of the Hospital of Incurables, and who formed the subjects of his experiments. In his observations or treatise, he gives a lucid statement of the moral and intellectual condition of his pupils, also accurately describing their habits. His task was an arduous one, and such as would have made many an individual shrink from attempting. He had to encounter a Babel of discordant sounds, hideous and unearthly cries, and the most determined resistance at first to control. But, in spite of every difficulty, his labours were attended with the most marked success, as the following will show in his own words. He says:—"1st. I have developed and applied, as much as the material means have permitted, the muscular system of the children. 2nd. The nervous irritability of several has disappeared or sensibly diminished. 3rd. They have walked, run, jumped, and begun different gymnastics, so useful in early years to young children. 4th. They have learned to seize hold of, handle, throw, and carry burdens, the weight of which

surpassed the strength of their age. 5th. Five among them have learned to read, write, count, to ascertain limit, which permits us to hope that they can still be improved by instruction. 6th. Their notions have become precise and enlarged. 7th. Ideas have begun to form themselves, and to be made manifest in their conduct and speech. 8th. Obedience and morality, which were loth to be created, have begun to regulate part of their acts and of their existence. 9th. Several are sought for in the establishment to perform manual labours, in preference to older persons, and are employed to work in the gardens. 10th. During the six months, nine of my children have been severely ill, and the health of all is strengthened. On a calm review of the labours of this excellent man, we cannot but be struck with the fact that obstacles which formerly appeared insurmountable in the education of idiots have been overcome, and the development of hidden powers have been made apparent, to an extent quite beyond human calculation.

What an amount of misery may be relieved in this our fallen world by the establishment of kindred institutions to elevate the creature from his isolated, forlorn and hopeless condition, to the social pleasures of life, the pursuits of science, and the advantages of education! How dignified the pursuit to commence and to operate in a work so great and noble, so distinguished, which shall have for its object the expansion and growth of the intellect, from the atoms of sunk humanity, and raise the standard of the mental and moral condition so as to render existence a pleasure, not a curse!

Once more I may refer to Dr. Alexander's work on Switzerland, lately published, in which he refers to a young German physician, Dr. Fruggenbuli, who has devoted his talents and his property to a great and noble purpose, for the benefit of youthful idiots. Such is his confidence to ameliorate the condition of this unhappy class of sufferers, that he has sold his property in order to purchase a house where he may conduct his benevolent object. There he resides with his family of idiotic children. The most encouraging results have followed, and by the published reports he has put forth of the working of his institution, and the testimony of those who have visited there, he has earned for himself a name in Germany amongst such as are best able to appreciate his disinterested labours. The public mind, through the press, needs only to be informed of the rise and progress of such institutions which have done so much for the benefit of mankind, and the alleviation of misery in its worst form, to be awakened to the importance of raising one of a similar character in this country commensurate with the wants of the population. It is not too much to hope that a benevolent Christian people, whose aims and purposes in the cause of philanthropy embrace the universe, will be alive to the appeals that are made on behalf of the poor, neglected, and wretched idiot, and, by a generous impulse of the noble and right-hearted feeling, decide that England shall no longer remain in the background, forgetful of the outcasts of society. Why not have an English Biotin started?

In conclusion I would recommend all who may feel an interest in these deplorable cases to procure Dr. Scott's manual of philoprosody containing a series of remarks on the education of idiots and children of wild intellect. There are also three most interesting papers on the same subject in Chambers' Edinburgh Journal for January and February, 1847, which are well worth an attentive perusal.

I remain, Sir, very truly

Tiverton, June 16

EDW. S. GRAY

GENERAL MEDICAL ANNUITY FUND

To the Editor of the Medical Times

Sir,—I have read with much pain the singular communication of Dr. S. Palmer, published in your journal of the 19th instant. I say, I feel

pain, because I had not the slightest idea that that gentleman left the meeting at Northampton with any sentiments inimical to our proceedings, or that all objecting to the free and unpartial manner with which his project was discussed. I must say, too, that he has misunderstood the feelings of the gentlemen present on that occasion, if he believes they came there with any predilection in favour of any particular system they were all open to conviction, and ready to adopt any principles which in their development and character were practicable and efficient; indeed, so highly do I estimate the goodness of heart and purity of feeling which actuate Dr. Palmer that I told him distinctly, that if he could verify his statements and prove the practicability of his plan, no man would rejoice more than myself, and nothing would afford me higher gratification, than to forego my own project and adopt his.

Surely there cannot arise a question in the heart of any man, whose object is the comfort of those he seeks to benefit, between granting the parties a large sum and a small one, but I tell him out hopes that might not be realized would be to sin against confidence and expectation.

Dr. Palmer's project, as far as we could understand it, was untenable, on the ground that he could not realize it by the proposed subscriptions, that he could not receive much help to the annuities proposed, and that to furnish such annuities would require a far greater amount of capital and annual payment than he had it all contemplated. It was proved to him the utter impracticability of insuring a sum even equal to the twentieth part of what he proposed, on the terms of his project, and I must ask, will the experience of the past justify any efforts to establish a society, which should guarantee a certain amount of advantage, where the resources are varying and uncertain, as they must ever be when principally derived from donations and bequests? Think, too, of the number of years which must roll away together with the originators and promoters of the plan before such a society as Dr. Palmer would establish could be in a position to grant assistance at all. Is it not better, then, to commence upon a small but certain scale, and to trust to time and the further growth of the institution for the development of more extensive benefits?

I am not aware that the secretary evinced any remarkable fluency of speech or logical sequence in proving these facts to Dr. Palmer. He drew his information from the Government tables, and pointed them out to Dr. Palmer with all the courtesy and kindness he could show, and spent much time and I will add evinced much ability in pointing out the untenability of the project, as far as that project was shown.

If he failed to convince Dr. Palmer he certainly was more successful in convincing the other auditor.

I have said, Sir, repeatedly, and I reiterate that statement, that I am wedded to the project that I have hitherto supported, I mean with all the power and ability I possess. I have seen none other supersede it. But the moment I do so, that moment will I abandon my own. Neither am I vain enough to pronounce it perfect, for what human institution is perfect? But I have seen nothing, yet which has induced me to pause, but everything to stimulate my exertion, and stimulated they will be, until the blessings I seek to bestow are scattered over the land, and come upon the desolate heart of the widow and the orphan like falling dews upon the parched desert.

Dr. Palmer speaks as though the smallness of our number at Northampton excited his melancholy, but Dr. Palmer is not ignorant of the great difficulty with which professional men are kept from their duties, and the vast distance which separated our leading supporters. It would, however, have been far of him to refer to the pile of letters which had been received from all parts of the kingdom, regretting unavoidable

absence, and all breathing one pure spirit of hope and expectation, and one cheering vein of implicit confidence in our proceedings, which ran through every communication. I read, therefore, this meeting as a vast meeting, if the mind be recognised as the noblest part of man, for many spirits were with us whose bodies were absent, and their written testimony lay open for inspection.

I think it somewhat unkind, too, of Dr. Palmer to convey to the world the gratuitous assumption that either he or his project met with unfair treatment for I know of none who denounced his project as "visionary or utopian, or who tore it piecemeal, and scattered it to the winds of heaven." When men appear before the public, anxious to propound views, or propagate peculiar opinions, they cannot but expect that those views and opinions must undergo the ordeal of criticism, nor have they reason to complain, if such criticism be conducted with fairness, even although it shall expose the vulnerable parts. It is illogical to wince on such occasions, for the great end of all controversy is to elicit truth, not to obtain victory. I have the greatest deference was paid to Dr. Palmer—the purity of his motives were never impeached, the excellency of his heart was never questioned, although it might be doubted whether the world in general could be influenced by the spirit which pervaded him, so calm, how idle it is with selfishness and apathy, neither was the known acquirements and acknowledged talents of this worthy and excellent gentleman forgotten in our admiration of his character, and I hold it one of the happiest circumstances of my life that my event should have given to me the honour of his acquaintance.

Dr. Palmer must pardon me if I complain of the captious manner in which he treats of the arguments of the mere arithmetician, and the blind calculations of the actuary. No institution flourish that is not subjected to the searching ordeal of mathematical correctness. How many beautiful societies have sprung up, flourished for a time, and then decayed, for the want of strict attention to this most essential consideration.

When my project was first mooted it was not done without deep thought and rigid calculation. It was done because I saw, or believed I saw, a great necessity for such an institution, and although the preparation of it has involved me in new cares and new anxieties, which were not contemplated at the time of its promulgation, yet I will not shrink from my toil or labour until my end be attained. My calculations then were simply on the annual guinea, and I regulated the amount of annuities by what they should produce, but it does not follow that we should never do it. No like Dr. Palmer, I look for some offering and bequests—I look for assistance from the 'pulent and the childless,' and I anticipate the gratification of doing much more than proposed, and such, too, are the feelings of my coadjutors, the subscribers to this fund, or why have many amongst them been most liberal in their donations, and exceeded the stipulated amount of subscriptions—why at this moment do I hold in my hand the munificent gift of Dr. Jephson, of 100 guineas, which that excellent and philanthropic gentleman instantly forwarded to the secretary on the receipt of the resolution passed at the Northampton meeting?

Accompanied, too, by a letter full of fervent wishes for the success of our institution. Let this noble example be followed by other opulent men, and the brightest visions of Dr. Palmer and, I would add, the earnest prayers of my unworthy self will be fully realized.

But, for all this, we have no right to form our calculation on such contingencies. If they come, let us be thankful for them, and use them to the best of our abilities in advancing the interest and usefulness of our institution, but do not let us place the fabric we wish to last upon any uncertain foundation. The directors of the General Medical Annuity Fund will alone be guided in their legislation by "the arguments of the arith-

On Monday evening an inquest was held before F. Sworder, Esq., at the White Hart Inn, Hertford, to inquire into the cause of the death of George Jeffreys, a middle-aged man, well known in the town, and residing, at the time of his decease, in the Old Workhouse-yard. The deceased was a member of a club holding its meetings at the Black Swan, and had been unwell for some time. He was attended by Mr P. Keilly, the surgeon to the club, who visited and prescribed for him up to Thursday, the 11th inst., the day before his death. The relatives of the deceased, being dissatisfied with some part of the medical treatment, made application to the coroner to institute an inquiry into the cause

of death, and the present inquest was held in compliance with the demand so made.

The jury, having been sworn in, proceeded with the coroner to view the body.

Upon their return to the inquest-room, Mr. P. Reilly and his brother, Mr. J. Reilly, of Ware, had arrived.

The Coroner said: It is my duty to inform you, Mr. Reilly, that the jury are desirous that Dr. Davies should be instructed to open the body, and analyze a portion of the medicine last taken by the deceased, which was contained in a bottle now in the possession of Mr. Superintendent Knight; they judge that to be the fairest mode of proceeding, and they wish to know whether you are willing to assent to that arrangement. I have sent for Dr. Davies.

Mr. P. Reilly: I presume you mean that should open the body, and that Dr. Davies should be present during the examination.

The Coroner: Certainly not; that is out of the question.

Mr. P. Reilly intimated that he should object to any other arrangement.

William Jeffreys, as the brother of the deceased, objected to Mr. Reilly making the examination.

Mr. Reilly was about to reply to this observation, when

The Coroner said: We must not have any discussion on the subject; I will arrange that.

Mr. P. Reilly: I am willing to submit to the wish of the jury; if they desire Dr. Davies to conduct the examination, let them express that desire, and I will abide by it; I only wish for justice.

The Coroner said that was the wish of the jury.

Dr. Davies having arrived, The Coroner repeated what had occurred. It had, he said, been proposed that Dr. Davies should make a *post-mortem* examination of the body of the deceased, and analyze the contents of a bottle now in the custody of Mr. Knight. Mr. Reilly was of opinion that he should make the *post-mortem* examination; but he (the Coroner) had told him that that was quite out of the question, as it would not be right to allow the person whose conduct was, in some measure, the subject of inquiry, to do that.

Mr. P. Reilly: I wish to do nothing but what is legal and just, and I refer to you, as the tribunal of justice, to decide whether I am not the person who should make the examination.

The Coroner: That is impossible; I propose that Dr. Davies be instructed to make the examination. Mr. Reilly, if he wishes, may be present, if he does not interfere improperly.

Mr. Sedgwick (a juror) concurred in the arrangement suggested by the coroner. The other jurors also intimated their agreement.

Mr. P. Reilly: What I wish is that I should myself superintend the *post-mortem* examination, on the understanding that I shall take no steps without Dr. Davies' consent. That is what it ought to be.

The Coroner: Dr. Davies will have my warrant to make the *post-mortem* examination, and to analyze the contents of the stomach and of the bottle. You, if you like, and if Dr. Davies has no objection, can be present, provided you do not interfere.

Mr. P. Reilly: Your own precedent in a case which occurred six months ago is against your present decision, by which you blast the opinion you then gave. I wish the question to be left to the jury.

The Coroner remarked that the decision to which Mr. Reilly referred would not help him at all; nothing could be fairer than the arrangement suggested.

Mr. P. Reilly: I want nothing but justice; I have nothing to dread.

The Coroner remarked that, in the case to which Mr. Reilly referred, he had wanted his brother to perform the *post-mortem* examination, to which proposition he (the coroner) objected; Mr. Reilly then named Dr. Reed, who

was at once assented to. It seemed to him that they should follow the same plan in this case, selecting an independent professional gentleman to make the examination, and allowing Mr. Reilly to be present, upon the express understanding that he should not interfere with it. The coroner then formally requested Dr. Davies to undertake the examination.

Dr. Davies said he knew nothing of the nature of the case, but would discharge his duty as a professional man to the best of his ability.

The Coroner (to Superintendent Knight): You will now hand over the bottle containing the medicine to Mr. Davies.

Mr. Knight: I will first show it to Mr. Reilly.

Mr. Reilly: I want to see nothing of it.

The Coroner: Hand it over to Dr. Davies.

The inquiry was then proceeded with. The first witness examined was

Eliza Walls: I live at Hertford; I am a married woman; my husband is transported. The deceased, George Jeffreys, was forty-two years of age. I cohabited with him as his wife: we lived in the Old Workhouse-yard, in the parish of All Saints. Last winter deceased had a heavy fit of illness with fever; he was ill fifteen weeks. Mr. P. Reilly attended him in his illness, and he recovered, and went to his work as usual. Last Monday morning he was taken very ill with a pain in his chest; he had an asthma complaint. He continued to work during the day, and in the evening he told me he had called on Mr. Reilly, and that he would send some medicine. The medicine came shortly afterwards. Deceased went to his club that night about half-past six, and came home about ten. He said he felt very poorly indeed, and went to bed directly, and took some of the medicine which Mr. Reilly had sent. It was a white mixture, like the colour of water, in a quarter of a pint bottle; there were four doses, and deceased took it all at intervals of four hours. He was much better on Tuesday, and told Mr. Reilly so on the afternoon of that day when he called to see him. Mr. Reilly said he was glad to find him so well as he was, and would send him another bottle of mixture, and that he thought would do. Another bottle of medicine came on Tuesday evening; it is the same one I delivered over to Superintendent Knight.

The Coroner: Was that medicine the same colour as the first?—Witness: No; the first was white, and the second red.

Examination continued: I gave two tablespoonfuls of that medicine to Jeffreys on the night of Tuesday, at about eleven o'clock; that was according to the directions on the bottle. About an hour and a half after Jeffreys took it, he said, "Oh, girl, what a pain I have got at my chest; it hoops up so that I can't get my breath." He continued to complain of the pain from that time until he died. He wanted me to give him the next dose at the third hour, but I was afraid, because he said the stuff was working about him. About the fourth hour I gave him another dose; and, after talking it, he said, "Oh, I shall die; this stuff will kill me." It made him worse and worse; he complained of his breath. I gave him no other medicine but that I had from Mr. Reilly. He said he was worse, and he would not take any more of that medicine. He did take some more after Mr. Reilly had been. I thought he would have died, and about noon on Wednesday I sent one of my neighbour's daughters to fetch Mr. Reilly. Mr. Reilly and his brother both came. Jeffreys told him that the bottle of medicine would kill him; that it had torn him all to pieces at his chest. Mr. Reilly then ordered me not to give him so much when I gave the medicine again, and I did not.

Mr. Reilly saw the medicine then—the very bottle I have given to Mr. Knight. Mr. Reilly then ordered me to obtain twopennyworth of the best mustard, spread a plaster, and apply it to Jeffreys' chest, and keep it there as long as I could. I did as directed, and kept the plaster on for twenty minutes. He also said he would send an emetic which I was to administer

directly. A packet came, and when I opened it I found two emetics; I gave deceased one, which did not operate; and in the course of an hour I gave him the other, which also failed to produce vomiting, but operated very much upon the bowels. It was about four o'clock on Wednesday afternoon when I gave him the last powder; he still kept getting worse. On Thursday, between eleven and twelve o'clock, Mr. Reilly came again, and said he thought of bleeding deceased, but whether he said he was too far gone, or too weak, I can't remember; I did not rightly understand him. He told me to get twopennyworth more mustard and some vinegar, and stir it up together, and clap it on him where the pain was at the chest. I did exactly as he told me, and kept the plaster on for half an hour. Another emetic was then administered to him, according to Mr. Reilly's directions, after taking which the deceased was very bad; the last emetic did not operate at all, and the application of the mustard did not relieve the pain. Deceased still continued to complain of the pain at his chest, and said, "That bottle of stuff had done him." He had no medicine beside that sent by Mr. Reilly on Thursday. In the afternoon, about tea-time, he got so bad I was afraid he would die, and I sent for Mr. Reilly. Mr. Reilly did not come, but sent his young man, who felt about deceased, and said, certainly he was very bad. I told the young man I was not satisfied with his coming, and that I wished to see Mr. Reilly. The young man then went away, and Mr. Reilly came in about a quarter of an hour. When he came, he said, "Poor man! how long has he been taken for the worse?" Jeffreys shook his head, and said, "Ah! that bottle's done me; that bottle's done me;" he repeated this three times in the presence of Mr. Reilly. Mr. Reilly said, "Pooh, pooh! George." He did not say what was the matter with the deceased; he looked at him, and was going to leave the room, to come down, when Jeffreys asked him "Whether he was going to send him anything more to take?" Mr. Reilly said, "No, not at present." Mr. Reilly did not stay with the deceased above five or six minutes, but did not send him anything more, and did not see him again alive. At eight o'clock next morning he was a corpse.

By Mr. Reilly: I did not see you shake hands with the deceased, or wish him farewell, and say "God bless you!" nor hear him say he should get better, or ask you whether you thought he would.

Mr. Reilly: What did I tell you when I came down stairs—did I not say, "George is dying"?—Witness: No, you did not.

Mr. Reilly: How many years have I attended you and your husband?—Witness: Five or six years.

Mr. Reilly: Did I ever ask you for any money?—Witness gave no answer.

By the Coroner: I knew Jeffreys was dying all Thursday, but Mr. Reilly did not tell me so; Mr. Reilly attended Jeffreys as member of a club of which he was the medical officer. I and my husband always paid him.

Mr. Reilly: During the period that I attended your husband, did you complain of being in great want?—Witness: Yes.

Mr. Reilly: Who relieved you?—Witness: That has nothing to do with the case.

Mr. Reilly: Did I and my brother—you are on your oath?

The witness made no reply; but, in answer to a question from the coroner, stated "That Mr. Reilly had attended her and her husband as private patients, and that she had bills to show that she had been accustomed to pay him for his attendance."

Mr. Reilly: Did not your husband express his gratitude to me for my care and attention to him?

Jeffreys (brother of the deceased): That has nothing to do with the question.

Mr. Reilly: But it has. You have not paid me the last two years' bills?—Witness: No.

Mr. Reilly: Did I ever ask you?—Witness: No.

Mr. Reilly: Did I not give you relief out of my own pocket?—Witness: You gave me one shilling.

Mr. Reilly: And how much for my brother?—Witness (so we understood her): Two shillings.

Mr. Reilly: Did I give you any rabbits?

The Coroner said these questions were beside the object of the inquiry; the only question bearing on this particular case was, whether Mr. Reilly's treatment of the deceased up to this time had been satisfactory. Did you ever (addressing the witness) have occasion before this time to make any complaint of Mr. Reilly's want of skill or attention to the deceased?—Witness: No.

Mr. Reilly: What did you say was the cause of death? Was it walking to London just before his last illness?—Witness: I don't know that I wish to know; he did not walk to London; he rode eight miles of the way.

The Coroner said there was no complaint made except in reference to the particular bottle which had been produced.

Witness: It was Jeffreys' wish that I should keep that bottle.

By the Coroner: The last time the deceased took any of the medicine was on Thursday. Mr. Reilly had told me not to give him so much the next time as I had upon the two first occasions, and so I gave him only a small quantity. That was before he had the emetic. I gave the red medicine to Mr. Mills. Jeffreys told me before he died to keep it, for no doubt it would be called for.

Mr. Reilly: Did I not tell you your husband's lungs were gone?—Witness: You said he was touched with asthma.

Mr. Reilly: Will you inform the gentlemen of the jury whether you were not stimulated to make the complaint by persons in the room?—Witness: Only by his own friends; we were not satisfied.

Mr. Reilly: Will you swear that you are not put up to this by a person who is unfriendly to me?—Witness: I do not know who are your friends, and who are your foes.

Mr. Reilly: Has Cheshier done so?—Witness: No; I have not been stimulated to it by any one; his sister and brother were not satisfied.

By the Coroner: I swear that I kept the medicine in exactly the same state as when it was delivered to me, and when it was last taken by the deceased, until I delivered it into the hands of James Mills; I put nothing into it. The deceased had nothing but toast-and-water and arrowroot besides; he had only toast-and-water on Thursday.

Mr. Reilly, somewhat warmly, charged Cheshier with having instigated others to institute these proceedings, when he was interrupted by the coroner, who said that such questions were not relevant to the case.

Mr. Reilly (to witness): Did not your husband say that I behaved to him as a gentleman and a friend?—Witness: Yes; you always acted as a gentleman, and he always thought well of you till the last bottle.

Mr. Reilly: Did I not attend him in all respects as a professional gentleman should?—Witness: Why, Jeffreys did say one day that you ought to attend him a little more, as he was so bad.

Mr. Reilly: What! three or four times every day?

By the Coroner: Deceased often expressed his satisfaction with Mr. Reilly's attendance.

After a variety of similar questions and answers precisely to the same effect,

The Coroner said that he thought it advisable that the inquiry should now be adjourned. Indeed, he thought that some injustice had been done to Mr. Reilly by the examination which had already taken place, as they were not in a condition to close the inquiry that evening.

Mr. Reilly (warmly): No; nothing is unjust; I want everything clear. So far as I am concerned I want the fullest and most minute investigation. I am confident that my conduct

has been that of a professional man and a gentleman, and that the result of the *post-mortem* examination will disclose such disease as is quite sufficient to account for death.

The inquiry was then adjourned until seven o'clock on Tuesday evening.

The adjourned inquest was held at seven o'clock on Tuesday evening.

After some preliminary proceedings, J. Davies, M.D., was called and examined.

His evidence was as follows:—I performed a *post-mortem* examination on the body of George Jeffreys about eleven o'clock this morning. I was assisted by Mr. Shillitoe. Neither Mr. Reilly nor his brother was present. I met Mr. Reilly last night, and asked him whether he would like his brother to be present, he declined either being present himself or sending his brother, and said he would be perfectly satisfied with my examination. On opening the outer part of the body, I found it to be that of a fine man of middle age; he was very fat. The liver was very much diseased, was very large, and had the appearance of being in what is vulgarly termed a rotten state; it was of a very dark, black, dirty colour. There was a little appearance of inflammation about the stomach. The disease of the liver had extended to other parts, and was adhering to the inside of the belly. I think the cause of death was a combination of diseases. I don't think there was any one distinct cause. The lungs, on the whole, were very healthy; the right lung was quite healthy for a person of the deceased's age; the left lung had a little cavity at the top of it, which betokened a tendency to decline, but in a very small degree at that age; it was not in that state, but it might have continued to perform its functions for a great number of years; there were no tubercles for the disease to extend to. The heart was rather larger than natural. The appearance of the stomach might have arisen from irregularity of living, or from taking a little too much drink. If the deceased had been of intemperate habits that would have accounted for the appearances. There was quite sufficient disease to account for death: the wonder was, from the quantity of disease in the liver, and about the belly, that deceased had lived so long. The cavity in the left lung would account for the asthma of which he complained; some of the bronchial tubes were partially ossified. I have not analyzed the contents of the stomach; to perform a complete analysis would take many days, but I have to a certain extent analyzed the medicine, by applying a few tests. It appears to be a very simple mixture; the colouring matter is "red sanders," which is used to make compound tincture of lavender, and is slightly stomachic; there is also a little ammonia in it; there is nothing in it which could injure the man, looking to the state in which he was.

The Coroner: The deceased said that the medicine caused violent pains in the chest.

Dr. Davies: I think that was the complaint; I have seen many similar cases, and I could not help forming an opinion from what the woman said last night. The medicine could have had nothing to do with his death; he had taken none for two days before, and very little of it then. It was a very casual analysis I made; I think the ammonia was combined with acetic acid. I smelt and tasted the mixture, and applied all the tests I could, but found nothing noxious in it; I think it was a proper medicine to administer; I see no objection to it. Medical men differ a little in practice.

Mr. Sedgwick (a jurymen): I presume that Mr. Shillitoe entertains the same opinion as yourself?—Dr. Davies: He does.

Mr. P. Reilly and his brother, Mr. J. Reilly, entered the room at this stage of the proceedings.

The Coroner immediately turned to Mr. P. Reilly, and said that Dr. Davies had just stated that the medicine administered to the deceased by Mr. Reilly was a proper medicine, and could have had no injurious effect upon the deceased.

Mr. P. Reilly (warmly): I should think so;

I should think I should not administer improper medicine.

The Coroner: If you respond to my courtesy in that way I shall not take the trouble of addressing myself to you.

The coroner was about to read over the evidence of Dr. Davies, when

Mr. John Reilly said: Having seen the deceased, you will perhaps allow me to state my opinion before that is read; I hope I may be able to give just as correct an opinion as the one you have received.

The Coroner: I have no doubt of that; but you can hardly give evidence, as you must be looked upon something in the light of a person interested.

Mr. P. Reilly: No, certainly not; he has no interest in the case.

The Coroner: I do not say that he has; I do not say that he would not tell the truth; but, nevertheless, he would be looked upon as a person interested.

Mr. P. Reilly: Very well; I am satisfied.

In answer to questions from Mr. Littlechild, a juror, Dr. Davies said there was not great disease in the stomach; it was a little more red than it ought to be; there was no disease of long standing there; the liver was most affected.

Mr. P. Reilly: If you, as a regular practitioner, treating a patient who might die in the course of your treatment, were subjected to an inquiry of this kind, instituted without your knowledge, would you not say that you were treated badly, and would you not feel hurt at such treatment—at such an investigation being instituted without any authority from the churchwardens or the overseers?

Dr. Davies: If that is a proper question in the course of this inquiry, I have no objection to answer it directly.

The Coroner: There is no objection to it.

Dr. Davies: Then I say that, if I had acted in the way that Mr. Reilly is stated to have acted in the evidence given by the woman last night, I should feel myself very much aggrieved indeed.

The room was then cleared; upon our return, William Jeffreys, the brother of the deceased, was examined, and entirely corroborated the evidence of the woman Walls, relative to the deceased's impression that the last medicine had been the cause of his death, and his injunction that it should be preserved. The witness added that the woman Walls was very kind to his brother, and that the inquiry had taken place at the desire of the deceased's relatives. There was a rumour about the town relative to the cause of Jeffreys' death.

The jury expressed their satisfaction with the evidence, and their unwillingness to examine any more witnesses.

The Coroner said he had called the last witness in consequence of the statements by the woman relative to the strong prepossession of the deceased, to see whether the deceased had made similar statements to others.

The jury then returned their verdict to the effect "That the deceased George Jeffreys had been deprived of life by the visitation of God, in a natural way." The foreman added that the jury wished to say they considered the case a proper one for inquiry, but that at the same time they were of opinion that Mr. Reilly had skillfully and properly attended to the deceased.

Mr. P. Reilly: Gentlemen, I thank you. I assure you that, after twenty years' experience, the circumstances that have characterized this case—the coroner's conduct—

The Coroner: If you are going to find fault with me, I shall not allow you to go on. I have been and am acting in the exercise of my duty, and I shall not allow you to insult me. I can conscientiously say that, from the circumstances detailed by the witness as occurring before the death of the deceased, there could not, in my opinion, be a more proper case for an inquest. The statement made respecting the man's strong prepossession as to the medicine being the cause of death induced me to call the witness who has just been examined, with a view to ascertain

the cause of death.

The Coroner: I have no doubt of that; but you can hardly give evidence, as you must be looked upon something in the light of a person interested.

Mr. P. Reilly: No, certainly not; he has no interest in the case.

The Coroner: I do not say that he has; I do not say that he would not tell the truth; but, nevertheless, he would be looked upon as a person interested.

Mr. P. Reilly: Very well; I am satisfied.

In answer to questions from Mr. Littlechild, a juror, Dr. Davies said there was not great disease in the stomach; it was a little more red than it ought to be; there was no disease of long standing there; the liver was most affected.

Mr. P. Reilly: If you, as a regular practitioner, treating a patient who might die in the course of your treatment, were subjected to an inquiry of this kind, instituted without your knowledge, would you not say that you were treated badly, and would you not feel hurt at such treatment—at such an investigation being instituted without any authority from the churchwardens or the overseers?

Dr. Davies: If that is a proper question in the course of this inquiry, I have no objection to answer it directly.

The Coroner: There is no objection to it.

Dr. Davies: Then I say that, if I had acted in the way that Mr. Reilly is stated to have acted in the evidence given by the woman last night, I should feel myself very much aggrieved indeed.

The room was then cleared; upon our return, William Jeffreys, the brother of the deceased, was examined, and entirely corroborated the evidence of the woman Walls, relative to the deceased's impression that the last medicine had been the cause of his death, and his injunction that it should be preserved. The witness added that the woman Walls was very kind to his brother, and that the inquiry had taken place at the desire of the deceased's relatives. There was a rumour about the town relative to the cause of Jeffreys' death.

The jury expressed their satisfaction with the evidence, and their unwillingness to examine any more witnesses.

The Coroner said he had called the last witness in consequence of the statements by the woman relative to the strong prepossession of the deceased, to see whether the deceased had made similar statements to others.

The jury then returned their verdict to the effect "That the deceased George Jeffreys had been deprived of life by the visitation of God, in a natural way." The foreman added that the jury wished to say they considered the case a proper one for inquiry, but that at the same time they were of opinion that Mr. Reilly had skillfully and properly attended to the deceased.

Mr. P. Reilly: Gentlemen, I thank you. I assure you that, after twenty years' experience, the circumstances that have characterized this case—the coroner's conduct—

The Coroner: If you are going to find fault with me, I shall not allow you to go on. I have been and am acting in the exercise of my duty, and I shall not allow you to insult me. I can conscientiously say that, from the circumstances detailed by the witness as occurring before the death of the deceased, there could not, in my opinion, be a more proper case for an inquest. The statement made respecting the man's strong prepossession as to the medicine being the cause of death induced me to call the witness who has just been examined, with a view to ascertain

the cause of death.

The Coroner: I have no doubt of that; but you can hardly give evidence, as you must be looked upon something in the light of a person interested.

Mr. P. Reilly: No, certainly not; he has no interest in the case.

The Coroner: I do not say that he has; I do not say that he would not tell the truth; but, nevertheless, he would be looked upon as a person interested.

Mr. P. Reilly: Very well; I am satisfied.

In answer to questions from Mr. Littlechild, a juror, Dr. Davies said there was not great disease in the stomach; it was a little more red than it ought to be; there was no disease of long standing there; the liver was most affected.

Mr. P. Reilly: If you, as a regular practitioner, treating a patient who might die in the course of your treatment, were subjected to an inquiry of this kind, instituted without your knowledge, would you not say that you were treated badly, and would you not feel hurt at such treatment—at such an investigation being instituted without any authority from the churchwardens or the overseers?

Dr. Davies: If that is a proper question in the course of this inquiry, I have no objection to answer it directly.

A COURSE

LECTURES ON SURGERY.

BY

SAMUEL COOPER, Esq., F.R.S.

Professor of Surgery to University College, London
Consulting Surgeon to London University Hospital

LECTURE VI.

It is my duty in this lecture to make some remarks on mortification—a term signifying the death of a part of the body, and generally restricted in its application to the soft textures, where the surgeon is able to treat it externally. When occurring in the bones it is called necrosis. When mortification takes place, the soft parts are converted into a dirty looking green or black mass, turbid, and having no longer any connection with the muscular and nervous systems. These parts become *sloughs* insensible to pain, and not partaking of the natural heat of the body. The term will lead you to understand the total absence of all motion, and the suspension of every function in the parts involved. At the same time it is worthy of remark, that, for the formation of one of these sloughs, the presence and agency of life is essential. But is, they can never only be formed in the living subject. The complete death of the part, and not only in annihilation of sensibility and power of motion in them, is involved. Since these two states may occur in putrefaction, in which the parts continue to live, the fluids still flow, and nutrition and absorption are carried on, and life, though existing in a slow degree, is not extinct. During the prevalence of cholera in London, we saw many patients in whom was interruption of the circulation—marasmus in certain parts, then mortification was apprehended, yet these parts have regained their healthy condition. Where the cuticle is not separated from the cutis, and no fetid gas is evolved, you may generally consider that mortification has not begun. The terms *gangrene* and *sphacelus*, though sometimes used synonymously, are more properly applied to the early and advanced stages of mortification respectively. The descriptions of mortification, as given in books, is too generally restricted to such changes as are apparent to the eye, and it is very probable that a truer pathology would lead us to include other processes among the symptoms of its existence, such as the softening of cerebral substances. Mortification may be either preceded by inflammation, or may occur without it. The former is called humid, inflammatory, or acute gangrene. John Hunter described it to be the mere action of the natural power of a putrid decomposition of blood to it. In case of mortification, however, it is the excess of the action over the power necessary to sustain it. The other gangrene, occurring without previous inflammation, is called dry or chronic, and sometimes, from the absence of any specific known cause, is termed

idiopathic, it usually arises from internal causes of this kind in the venous system, and that which arise from the action in the system of destruction of blood. Considering this disorder in its cause, we may divide the subject into three heads, first, the stoppage of the circulation caused by the violent action of external agents, whether mechanical, chemical, physical and third from the action of certain putrid inflammation, and lastly from mortification, or rather a stoppage of circulation, though it may be called upon properly considered in regard to its origin, it proceeds from the same cause as mortification. We may often conclude that it is the result of certain humors, the weakness of the part, and the tendency to apply of the venous system, obstruction of the circulation, and that of the cutis, where inflammation is so situated, the action of the death of the part. Healthy phlegmonous inflammation is not followed by mortification, although when it extends, it is unusually severe, and produces a violent reaction, and a more violent inflammation. When a mortification takes place, it is a violent external injury, a deep wound, fracture, or laceration of the soft parts, or a deep ulcer, followed by inflammation in the part, and a swelling and tense, the cuticle is the first to be affected, and very darkened, the cutis is so, and becomes of a dark purple. The living humors, to black, the inflammation is destroyed, and putrefaction commences. You know at what animal life is gone, the parts become subject to the laws of chemical decay, according to which they act and react on each other, thus air is generated in these, and putrefaction may be observed, and they are filled with the fingers crackling. It may be heard, or it is heard, but not distinguished, the parts are in a fluid state. A third kind is called *dry*, even off during mortification, owing to the temperature and the kind of fluid which is always present, and gives rise to humid gangrene. In all the forms of mortification cellular tissue suffers more than skin or muscle, which may be owing to their superior vascularity rendering them more functionary in life. When the dead parts are about to be separated from the living, a red line, often very thin, appears just at the edge of the slough between the sound skin and the destroyed tissue, this is called the line of demarcation, and shows that the severe inflammation has taken place in the skin, and the slough. It is in appearance what is called for by the surgeon with much anxiety. Some of the formation of the line, the parts appear, like very small ulcers, which, uniting together, make a hollow, extending round the dead parts, which extends in depth until the patient lives long enough, it effects the complete separation of the slough, this is accomplished by the action of the absorbents, by a process not unlike that of ulceration, a discharge of serum, and afterwards of pus, takes place from the line of detachment, increasing as more of the subjacent substance is

exposed. The detachment of the slough takes place at various periods after mortification has commenced, sometimes, indeed, not till after a long time has expired.

The constitutional symptoms attending gangrene are very remarkable. When any considerable portion of the body is involved, the whole system suffers great derangement and depression of its powers. It violent inflammation has preceded mortification, sympathetic inflammatory fever commonly attends its first stages, which generally subsides when sphacelus becomes more marked, an oppressive, violent, and frequent hæmorrhage informs the surgeon, if other symptoms are wanting, of the mischief which is going on. This symptom was formerly regarded as an infallible proof of the existence of gangrene in cases of strangulated hernia, but you are not to suppose that the hæmorrhage is mortifying merely on this evidence. The patient's countenance wears a wild cadaverous air, the stomach is disordered, and vomiting may occur, the intestinal contents are tensely distended with gas, the pulse is weak, rapid, and irregular. There is often pain at the region of the heart, and sometimes the bowels often a black matter proceeds from the intestinal canal. You are not to expect to find the same train of symptoms, either local or constitutional in every case. Much depends on the extent of mortification, and the situation and function of the part attacked. A highly organized texture will exhibit the symptoms more rapidly, and in a higher degree, than one less so. We have already seen that cases of mortification may be comprehended under three heads, resulting respectively from obstruction of the circulation from the violent action of external agents, and from the presence and action of poisonous substances in the system. You know that in inflammation, whether of the acute or chronic kind, there is interruption of the capillary circulation, this is one of the causes of mortification, so also when it is of a specific or malignant nature, as in carbuncle. Frequently it attacks the soft parts, when the patient has been long confined in one position, as we often see in cases of typhoid fever, or after severe injuries of the spine. In this case gangrene may be the result of debility, together with long-continued pressure on the parts, which obstructs the circulation. Patients often suffer in this way from mortification over and about the sacrum, os ilium, and the spines of the scapulae. Sometimes injurious pressure upon arteries results from negligent tying of bandages, which are made at first too tight, the part becomes flaccid and pale, loses its temperature, afterwards it decreases in size, becomes black, and perishes. The greatest care should invariably be exercised in placing ligatures, and some allowance should be made for swelling, for, though the bandage may be slack at first, by the rising of the part it will become tightened, and, if you wet the bandage, you should expect its tightening in drying. Other cases of mortification follow severe mechanical or chemical injuries; sometimes, indeed, the violence is sufficient to destroy at once the part

struck, as when a gunshot enters the body it frequently destroys the fibres in its track at once, which become sloughs, and require separation in order to the healing of the wound. Compound fractures again furnish us with other similar instances; the mortification following injuries of this kind is called *traumatic gangrene*. Cold is another external cause of mortification; but from all experience it would seem that the too early approach to the fire is in these cases the true cause of gangrene, the cold predisposing to that disorder. Baron Larrey has afforded us some valuable information on this subject in his "Observations on the Battle of Eylau," where the French soldiers suffered very severely: their feet, noses, and ears being attacked with gangrene after freezing. He states that for the three or four cold days before the battle, and until the second day after it, although the mercury in Reaumur's thermometer had fallen from ten to fifteen degrees below zero, none of the men complained of any of the symptoms of freezing, although they had passed three days and four of the nights in the snow and frost. On the 9th of February the temperature rose, and on the 10th a brisk thaw set in, and a vast number of the men began to surround the ambulances, complaining of acute pain and pricking in the feet, with numbness and the other signs of mortification. These facts are borne out by other experience, and may serve to satisfy us that cold is a condition of mortification, and a rapid rise of temperature the exciting cause. Another kind of mortification, very common in some continental countries, results from the use of diseased or spurred rye, in which the grains have become black and horny. It generally attacks the lower extremities, in which a burning pain is felt after a time this subsides, and the parts become cold and black, and slough. It is very rare in this country, but is deserving of the notice of the inquiring student.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILKINSON, M.D. (Edin.). M.B.S.
Physician to the Royal Infirmary for Children, &c. &c.

(Continued from p. 330.)

GENTLEMEN.—I intend occupying your time to-day with the consideration of that interesting and important in dady, commonly called *hydrocephalus*, or *water in the head*. You all know that when a child's brain is examined, who has died from this affection, in a great many cases there is found a preternatural amount of fluid in the ventricles, and in some beneath the arachnoid. This amount may vary from 3ij. to 5vj. in one class of cases, to upwards of three pints in another. The former quantity is found in that form of the disorder usually called *acute*, the latter in *chronic*, *hydrocephalus*. From the presence of this fluid the disease receives its name. It is, nevertheless, in a strict sense, a bad name, inasmuch as in a great many cases of acute hydrocephalus we do not find more fluid in the ventricles than natural, and even when we do it does not constitute either the pathologic essence of the disorder, nor can we always attribute to its effusion the fatal event or the more important of the previous symptoms. You will see then that *dropsy of the brain* is sometimes no dropsy at all.

Under this term of *hydrocephalus* several diseases are included, very different in their nature, and, although one or more lesions are common to all, yet, of course, we must separate these diseases one from the other. I shall at once break off the *chronic* form from the others, with which you know a child may be born and exist with for years, until its head becomes as large as its belly. To the so-called *acute hydrocephalus* I shall at present confine your attention.

Under this term varieties of two important affections are being constantly confounded or mixed up together, viz., *simple acute meningitis*, or *meningo-encephalitis* of a primary and secondary character, 2nd, *tuberculous meningitis*, of a sub-

acute character when viewed in reference to the former. These are two essentially different diseases: with the one—the latter—I am very familiar; of the former I have comparatively slight acquaintance, having within the last three years had but four cases. The former is a simple common inflammation of the membranes of the brain, and sometimes of the brain itself; the latter constitutes the disorder we usually see as the so-called *acute hydrocephalus*. Suppose a child of between two and six years of age, previously of good health and constitution, unmarked by scrofulous characteristics, is suddenly attacked with high fibrile excitement, accompanied with great agitation, extreme headache, and vomiting, but no previous constipation to speak of; that the countenance becomes exceedingly anxious, the lips and nose dry and arid, and the thirst great; that these symptoms rapidly progress, delirium supervenes, and this acute in character; that partial or general convulsions come on, and coma gradually closes the scene; or it may be that, with proper and active treatment, the disease is cut short and the child recovers; but that, if it dies, the disorder runs its course in from thirty to fifty hours, and after death, a small quantity of clear or turbid fluid, or even pus, is found in the ventricles, the ventricular lining membrane injected and soft, or that upon the convexities of the hemispheres you find marks of inflammation with semi-fluid pus lying there, or great congestion of the cerebral vessels, &c.: in such a case you have an example of *simple primary meningitis*.

Suppose again a child of a constitution like the above: has been ill with remittent or other fever, or with pneumonia or scarlatina; suddenly in the course of the malady the face becomes anxious, the agitation great, febrile exacerbation increased, the head rolled about, the brows knitted, the supervision of delirium, jactitation, twitchings, or convulsions, then quietude, coma, and death, and this within a couple of days, you have an example of a *secondary* form of the above disorder; or it may be that with proper treatment the disease is arrested. After death you find it like to the former. These cases are called *hydrocephalus*, and they and their varieties are those which you read about being so satisfactorily treated. But they do not constitute the common hydrocephalus which you will generally have to treat; they are not the common forms *water in the brain*: this is another disorder altogether; and it is this which, when I talk about hydrocephalus or use this term, I always imply. What this is in symptoms and pathologic nature I shall now proceed to tell you. I shall begin with the following illustration:—

A child who has been *apparently* in good health though betraying to the practised eye marks of a weak or scrofulous constitution, or, on the other hand, who has already presented external manifestations of open scrofulous disorder evident to every one, is brought to you by its mother because it has become all at once inclined to rest, and is less vivacious than before. Its mother says it does not "go about as it did," does not take so much notice as it used to do of it likes to keep in her arms, to lean its head against her breast, or, if older, will not hold its head up from the table. It has been sick, often continuously rejecting everything from the stomach, and the mother recalls that the bowels have not been lately moved, though she still lays more stress on the indolent habits of her child. From the continuance of the constipation and sickness she gives it medicine; still no effect is produced. On regarding attentively this child you will, perhaps, find that the head is rather large; the veins ramifying over the scalp all large and blue; the hair fair, scanty, and fine. On putting your hand over the anterior fontanelle, if the child is young, and the ossification not complete, you will find it largely dilated, raised up considerably, and often pulsating with considerable force and volume. The scalp is warmer than natural, the brows very likely knitted, and the child does not like exposure to the light. The face is pale; delicate in complexion; and, in fine, the *artistic* characters of

the scrofulous diathesis are more or less betrayed. Now the vomiting begins to cease, but the constipation still continues; the child constantly hangs its head about, or rests it; often cries or moans in a peculiar manner; puts its hands to its head, or throws them about, or picks its mouth, nose, &c., and there is much somnolency. Sometimes the head is rolled about, or shaken continuously from side to side, or is forcibly buried in the pillow. Next, the child is aroused with difficulty; it grinds its teeth; the thumbs are inverted, and jactitations often frequent. The face becomes paler; the child lies continually in a state of stupor, or, if it can be aroused, it opens its eyes, stares wildly or fixedly, and goes off again as before. It passes then into a constant state of stupor; it squints; one pupil may be dilated, the other contracted, or both may suffer considerable dilatation; then occur convulsions or paralytic. The respiration is irregular, suspicious, sometimes stertorous; some urine and scanty stools are passed involuntarily; mucus hangs about the mouth; the face becomes rather blue, or is deadly pale, often puffy; again, slight convulsions or twitchings supervene, and the child dies. The disease runs a comparatively prolonged course, sometimes even a month, in other cases six or seven days. Under the most careful management, under the most diversified forms of treatment, little will be found that can hinder the fatal event.

In the same way that you may have simple acute meningitis of a secondary or intercurrent form, so may you have the scrofulous disorder of the meninges occurring as a secondary form too. A child passing through remittent fever, pneumonia, &c., may present the above series of phenomena, or modifications of them, and after death the brain presents lesional appearances analogous to those of the primary form of the disorder. These appearances, which I shall refer to presently, are such to lead to the opinion that the common hydrocephalus of great towns particularly, as occurring in the offspring of the lower orders, is a disease dependent upon that peculiar constitution of body we call the *scrofulous*; that the local disorder consists in the deposit of tuberculous granulations, or confluent or semi-confluent matter closely allied to tuberculous exudations, accompanied with inflammation of a scrofulous character. Before alluding in detail to the morbid appearances, I shall analyze more particularly the symptoms of the disease. A person accustomed to see much of this disorder will soon discover that its symptoms may be arranged with facility under three heads, and, although one of these divisions is completely arbitrary, yet it is of practical importance, notwithstanding. Under the first head may be arranged those signs or symptoms indicative of encephalic disturbance; under the second, those arising from the secondary disorder of the digestive apparatus; and under the third, the condition of the circulation, respiration, &c. &c. In the table before you I have placed the chief of these symptoms under their particular heads:—

Encephalic Symptoms.

Headache.
Increased sensibility of the organs of special sense.
Somnolency, stupor, coma.
Convulsions, &c.
Delirium.
Paralysis.
Strabismus, &c.
Loss of senses—special.

Gastro-intestinal Symptoms.

Vomiting.
Constipation.

III.

Other Signs.

State of pulse.
State of respiration.
State of fontanelles.
General aspect, &c. &c.

I shall speak of these and correlated symptoms, as far as I can, in their order of progressive oc-

currence; but you must remember that, although tuberculous meningitis is in general a well marked and easily-diagnosed malady, yet in some cases the diagnosis is by no means easy. What I state, also, may differ somewhat from writers upon the subject; but, as these lectures are not *systematic*, I may be allowed to speak chiefly from my own experience.

Headache is a constant symptom, and one of the first that makes its appearance in the child. Reasoning about it, however, we labour under much disadvantage, since we have to glean a knowledge of its existence in many cases from circumstantial evidence alone. But the mother's phrases of "banging about its head," "so heavy in the head," "it seems so quiet," "puts its hands to its head," "will not hold up its head," together with the dulness, apathy, crying, and disinclination to leave the nurse's arms, with tendency to sleep, are to me all many evidences of the presence of a degree of cephalalgia. The latter, however, I do not think is generally severe or acute; it is more *dull*, more frequently partial than general, and *frontal* than otherwise. I have seen it *vertical*.

Morbid sensitiveness of the eye and ear is very characteristic of the earlier period of the disease. The increased corrugation of the brows upon turning the child to the light, the closing of the eyelids even under diminished intensities of the same, the apparent increase of pain or headache in bright light, the turning in of the face to the breast of the mother or to the pillow of the bed, are so many proofs of increased sensibility of the organ of vision.

Somnolency sometimes is present at first; at other times we have rather wakefulness than a tendency to sleep; though, again, the latter may be sometimes very great.

Vomiting is one of the most important and earliest signs of the disorder; it very soon makes its appearance after those I have already mentioned; so slight, apparently, are the latter sometimes, and so early prominent and severe the vomiting, that this is the symptom to which attention is first directed, and first excites the attention both of practitioner and mother. I cannot enforce too much attention being paid to it.

Next in importance to vomiting comes *constipation*; in fact, much of the value of either, as symptoms, is their coexistent existence. I am disposed to rank constipation as equal in the frequency of occurrence to vomiting; and I am quite ignorant of those cases in which *primary tuberculous meningitis* is ushered in by diarrhoea or is so accompanied during its early progress. Constipation often precedes the headache, continues long after the vomiting has ceased, and is often great in the extreme, and, after purging and purging the patient, small or infrequent evacuations are only obtained. In other cases after the first few days, the bowels become more readily moved; in still fewer, towards the third period of the disorder, they become relaxed. I cannot agree with those writers who lay so much stress upon the "dark green stools," "stools covered with an oiliness or glossy bile," a "dark green gelatinous evacuation," as diagnostic of the disease; nor can I ascribe the importance which some do to the "retracted state of the abdomen." As for placing either of these symptoms in comparison with vomiting and constipation, it is out of all question, and the condition of the abdomen, when it does occur, is seen only after the first six or seven days, and bears more reference to the approach of the fatal event than to the diagnosis of the previous disease.

These, gentlemen, are the most important signs of the first stage of the disorder; and if you have a scrofulous-looking child brought to you, with vomiting and constipation, headache, &c. &c., place your hand upon the anterior fontanelle: if it be large, tense, or convexly raised, pulsating with volume, there can be no doubt about the disorder, and which is further proved by the head being larger and warmer than natural, the veins larger and bluer, and the hair fine, but scanty.

The chief thing which you have to guard

against will be that you do not mistake the vomiting and constipation for signs of primary disease of the gastro-intestinal apparatus, and look upon the cephalic signs as secondary upon them: the fact being quite the reverse. In some exceptional instances vomiting is absent, as in a remarkable case of Schwenginger's, in which the disease commenced with coma, and during the whole course of it there was neither vomiting nor cephalalgia; and yet, on examination after death, there existed the three more commonly observed lesions, viz., granular deposits, softness of the cerebral centres, with effusion into the ventricles. On the other hand, the continual vomiting is sometimes so prominent and overwhelming a symptom as to alone attract attention.

The reviewer of Burton's work, in "Forbes," says:—"In our earlier practice we treated a fatal case of hydrocephalus, the exact nature of which was so masked by incessant and extreme vomiting that we could not be persuaded of its real character until we saw the ventricles full of fluid after death." Dr. Bennett, who, by-the-by, has written one of the best monographs on hydrocephalus, thinks that vomiting is most characteristic of cases attended by effusion of lymph at the base of the brain, and around the medulla oblongata.

The symptoms I have thus spoken of in detail are the more prominent ones which mark the first step or period of the disease. Those marking the second are, first, *stupor*. In some degree or other *stupor* almost always exists; in very rare cases it is wanting; I have observed it absent in one only. Sometimes the child will be quite quiet for a long time; at others, every now and then it will shake its head from side to side, or force it into the pillow, or grind its teeth. I have generally observed the vomiting on the supervention of stupor to cease.

The whole series of *convulsive phenomena* met with in the course of this disease are in some relations difficult to reason on. Sometimes severe general convulsions supervene, either late or early, in the disease; at other times convulsive actions of a single member, or only twitching of the eyelids, or of the angles of the mouth; sudden snapping together of the jaws and immediate relaxation, grinding of the teeth, rolling of the eyes, opening and shutting of the eyelids, &c., come on only at an after period. In some cases inversion of the thumbs upon the palms, or flexion of the toes and feet, are observed early. In this disorder you may see the phenomena of excitomotor action range from a little quivering of the eyelid up to perfect *opisthotonus*; but none, however early they may appear, occur before headache and constipation. I have now a case under my care in which the child is constantly shaking its head, and tearing and pulling its face with its hands. This motion of the head came on very early, but with previous obstinate constipation and knitting of the brows.

The accession of *coma* marks another stage of development; but sometimes it comes on very rapidly indeed, after headache, piercing cries, knitting of the brows, pulsating tense fontanelles, constipation, and vomiting; so that the first stage seems to run at once into the last. It does not always continue unbroken until death, for what we must call, even in the child *delirium*, and convulsions appear intercurrently; but again, as I have said, the coma may be a deep quiet passage from life unto death. I think I may pretty confidently assure you that when deep coma passes off, being replaced by convulsions, or delirium again comes on, quick dissolution is indicated by the secondary accession.

Partial or temporary loss of power and motion of one or more members is often seen, but perfect and persistent *paralysis* is, I think, rare. Still I have observed an instance of complete hemiplegia in a girl of three years and a half of age. It came on early in the disease, first in one extremity, then in the other, and was preceded by inversion of the thumbs.

Some persons lay great stress upon *squinting*,

and a peculiar state of the pupils. Any frequently or permanently altered condition of the visual organs only becomes prominent during the latter period of the disorder, and, I think, in most cases shortly before death. Temporary *squinting* is common enough; but still, as far as my experience goes, what I should call true *strabismus* does not exist so often as some suppose. I do not look upon the mere turning up of the eyes as this proper strabismus, but persistent, abnormal *convergent*, and *divergent* states of their axes as such. The pupils are more often unequally dilated than there is strabismus; and, generally, one pupil is far more dilated than the other, although the latter is more so than in health. The sense of vision is often lost altogether, or at least the contracting power of the iris is, late in the disease. I have not arrived at any conclusion as to the senses of hearing and smell.

When the child, after presenting symptoms like the above, lies on its back quite quiet, with the exception of now and then suddenly snapping its mouth—when the face becomes pale, or bluish and puffy, and glairy mucus hangs about the mouth—you have precursors of a quick event that our art is baffled to avoid.

I have, as you, perhaps, may have remarked, passed over the state of the pulse and respiration affording you signs of importance. I may be long, but I have no fear in asserting that the pulse is secondary to all the phenomena I have spoken to you about. Without many of the latter we could never arrive at the nature of the disease, whatever was the state of the pulse. With them we do not require to consider the latter at all. I never notice it save at the close of life, and then I can pretty well glean from other circumstances the nature of the future. Only look to the writers on hydrocephalus, and you will find the most discordant statements as to the state of the pulse, whether at the onset or termination of this disorder. As far as my experience goes, the following axioms laid down by Killiet are pretty correct:—

1. The pulse is moderately accelerated at the commencement.
2. Irregular, with or without slackening in the middle period.
3. Much accelerated and very small shortly before death.

I shall add, however, that in some cases I have felt it very slow and languid before death.

Although I cannot say that in the earliest stage *inequality of respiration* is a distinctive feature of our present malady, yet I regard it as very characteristic of it in its third period, and that in a few cases it is present from the first. I particularly drew attention to the value of it as a sign in a case which I read before the Medical Society of London, which I shall, perhaps, at my next lecture speak to you about, but which you will find noticed in the 4th vol. of Dr. Ranking's Report, at p. 333, together with the observations of a very great authority, M. Trousseau, on the same symptom, as well as another, viz., a peculiar redness of the skin on the slightest friction; which latter, by-the-by, I am ignorant of. It is not alone quickness, laboriousness, or slowness, that are observed in connection with respiration, but rather a *sighing* re-spiration in elder children, or in younger a hurried unequal breathing, sometimes alternating with a slow and heavy performance of the act. There is often a momentary suspension apparently of all respiratory function, the child appearing as if the chest did no duty at all. In some cases *stertorous* breathing is seen, and I have read of *rattling* and *whistling* respiration.

The general heat of the body is, like the pulse, subject to much change, sometimes being greatly increased, at others diminished. I have not noticed a fetor of the breath, as spoken of by some French writers; but this, if it exist, is to be attributed in all probability to the frequently adopted plan of mercurial treatment. Nor am I aware that the teeth gums, tongue, or appetites of hunger or thirst, present any peculiar,

constant, or particular relations to the disease we are considering.

Of the presence of the general disturbance *fever* I shall speak of here after.

DUMAS ON ORGANIC CHEMISTRY

No. XXIV

(Continued from page 311)

ON MILK—(continued)

Alcohol, tannin, and metallic salts throw down precipitates with milk either by robbing it of its water or by combining with the casein.

Many plants are capable of coagulating milk. Usually they produce this effect by the acids which they contain. Some, however, which do not offer any acid reaction, as the flowers of the artichoke and the thistle, still possess the power of which we are speaking. It is a remarkable fact, that, if we prepare the infusion of these flowers hot, it does not coagulate milk although a cold infusion acts the more rapidly and effectually when the milk has been previously heated. The *goutte de lait* possesses the property of turning milk sour, and rendering it so viscous that it may easily draw it out in threads. When once this operation has been performed in any wooden vessel the latter preserves the power of propagating this action to fresh milk when introduced into it. So also does the milk itself, which has been thus modified, induce a similar alteration in other milk when brought into contact with it.

In some of the northern provinces of Sweden they make use of milk in this state as an article of food. It has received the name of *lut*.

Of all the bodies which determine the coagulation of milk, none acts in so remarkable a manner as rennet, one part of rennet in fact will coagulate 30,000 parts of milk.

Rennet, such as we usually meet with is a very complex acid liquid, it contains hydrochloric acid, lactic acid, some fatty acids, earthy salts, silicic acid, and hydrochloric acid, also, in a combined animal substance which it especially owes its property of coagulating milk. This body has received the name of *hymosine*, its characters resemble those of *pepsine*—if, indeed, these two bodies are not

identical. Hymosine is insoluble in water, alcohol, ether and in the oils. It is dissolved by water slightly acidulated, the alkalis precipitate it from this solution in flakes. In milk, in like manner, throws it down. It reduces iodine to the state of iodide.

As to the presence of this substance in the mucous membrane of the stomach of animals, as well as the liquid of the stomach itself, owes the property of precipitating milk.

It must be employed, sometimes in the liquid state, sometimes dry. The following is the method of preparing it.—We take the stomach of a calf which has been fed only on its mother's milk, we detach the clots and wash them in fresh water. After having wiped them with a very clean cloth, they are to be salted and put back again into the stomach, which should then be dried and put by for use.

The minute quantity of rennet, whether liquid or solid which suffices to excite the coagulation of milk, explains how it happens that the porous earthenware vessels, or even those which are made of wood which have once been used in the process may serve repeatedly for the same purpose, and even determine the coagulation of the milk, without the necessity of adding any fresh rennet. During the maturation, there is formed a peculiar ferment which belongs within the pores of the vessel in which it is not formed, but by repeated washings.

We may here make one remark. The nature of the serum which separates in the precipitate caseous and fatty matters, which has been effected by means of rennet. According to M. Scherer we have only a little acetic acid for serum, and it is very temperature to be at 75° C. and we have a coagulum as well with properties intermediate between those of albumen and casein. But the property of the substance thus precipitated is different in all respects.

So far as we know, when thrown down by acetic acid, in Switzerland they use this milk in making cheese and butter. It is very named. In some parts of France, the serum from which the first precipitate has been extracted is separated, and then coagulated anew. They thus procure a cheese of inferior quality, known under the name of *fromage*, and which is chiefly consumed in the West.

Hitherto we have been speaking of normal milk—that is to say of milk such as it is when secreted by the female some time after bringing forth her young, but before the birth, and even for several days afterwards, the milk offers some peculiarities worthy of interest, in this state, it has been designated by the name of *colostrum*.

The colostrum differs from milk, inasmuch as it holds in solution a remarkable quantity of albumen, thus, it becomes coagulated by heat. It contains but little, if any, sugar of milk, it appears, in general, to be richer in salts than ordinary milk. According to most observers, it putrefies very rapidly, without presenting any acid reaction. As the property which the milk possesses of turning acid, on exposure to the air, is due to the presence of sugar of milk, we may presume that, when the colostrum becomes acid, it contains a certain amount of this principle. Some observers have even affirmed that the colostrum is richer in sugar or milk than is the milk itself, they have also made the same observation with regard to casein. These assertions must, however, be received with reservation. It is deplorable to remark, that the milk may be secreted independently of putrefaction or even of putrefaction, by a simple maturation of the breasts. We thus understand how it happens that, in some females, the secretion of the milk takes place during gestation, or within a short time of parturition.

The colostrum not unfrequently contains traces of blood. We find it at large mammarium lobules composed of a large collection of numerous lobules and of fatty globules, these lobules are covered by a thin layer of epithelium, the whole is covered by a thin layer of epithelium, the whole is covered by a thin layer of epithelium. The colostrum is provided with many large when treated in a mortar, the colostrum becomesropy, and may, under no circumstances, form a precipitate by the action of this reagent.

The colostrum appears to act as a slight purgative.

The following table by M. Simon, presents us with a comparative view of some of the characters of the colostrum and of the milk.

Synoptic Table, indicating the Physical and Chemical Properties of the Milk of the Cow at different periods before and after Parturition

Date.	Color	Taste	Acidity (pH)	Weight (g)	Volume (ml)	Softness	Albumen	Lactose	Sugar of milk	Lactic acid
42 days before parturition	Yellowish blue	Fresh in color	100 to + 0	Coagulated (lacteal)	78.1	200 to 500	Soft and persistent	Albumen	0	0
32 do	do	do	100 to + 0	do	78.1	do	do	do	0	0
21 do	do	do	100 to + 0	do	78.1	do	do	do	0	0
11 do	White	Sweetish	1040 to + 5	Partly coagulated (lacteal)	78.5	do	More solid	0	Casein	Sugar of milk
— days after do	do	do	1039 to + 5	do	78	do	do	0	do	do
1 do	do	Sweet	1039 to + 5	do	78	do	do	0	do	do
6 do	do	do	1039 to + 5	do	78	do	do	0	do	do
20 do	do	do	1039 to + 5	do	78	do	do	0	do	do
21 do	do	do	1039 to + 5	do	78	do	do	0	do	do
30 do	do	do	1039 to + 5	do	78	do	do	0	do	do

The colostrum has been analyzed by various observers, we will here select the results obtained by MM. T. Simon (Lilley), Simon (Lilley), pp. 281—283), Chevallier, Roux, Bousquet, and Le Bel.

M. Simon's analyses are as follows:
 Colostrum of cow
 Water 835.0
 Fatty matters 10.0
 Casein 10.0
 Sugar of milk 10.0
 Ashes 1.0

M. Simon does not say whether the colostrum

in the above case, was coagulable or not by heat.

Colostrum of a sheep
 at 4 days before parturition
 Water 877.0
 Fatty matters 8.0
 Casein 28.9
 Albumen 198.3
 Extractive matter 18.4
 Lactic acid 28.6

MM. Chevallier and Roux analyzed the colostrum of the cow, the ass, and the goat, the following were the results they obtained—

Colostrum of the cow
 Water 800.0
 Albumen 100.0
 Mucous matter 20.0
 Sugar of milk 10.0
 Fatty matters 26.0

1000.0 1000.0 1000.0

That which I have called albumen, in these analyses, is the matter coagulable by heat, some authors have described it under the name of casein, but, properly speaking, casein is that substance which has been denominated *mucous matter*.

exception of those found in the large intestine, which is most probably owing to the sulphuretted hydrogen which they contain. So adverse is this gas to endosmosis that the use of a membrane which has been in contact with it, even though for a very short time, will positively prevent its manifestation.—*Dutrochet*.

Dutrochet sought to measure the energy with which liquids penetrate, by the endosmotic process, from the exterior to the interior of the tube. He employed a tube of two millimètres in diameter, and graduated in divisions of two millimètres each; the membrane covering the lower, funnel-shaped, extremity of the tube measured forty millimètres in diameter. A solution of sugar, of a density of 1.115, rose 34 divisions in the space of one hour and a half; another solution of sugar, of a density of 1.224, rose 53 divisions in the same space of time; a third solution of sugar of a density of 1.083, rose 19½ divisions in the same space of time. Whence it evidently results that the energy and rapidity of the endosmotic process is directly proportional to the excess of the density of the liquid within the tube over that of the water without.

Dutrochet made, moreover, several experiments with various aqueous solutions of one and the same density, with a view to ascertain the respective intensity of their endosmotic action upon water. The following table shows the results of these experiments:—

Solution of gum acts with an intensity =	3
" sugar	= 5.17
" sugar	= 11
" albumen	= 12

In the course of his experiments on endosmosis, Dutrochet had occasion to observe that the direction of the endosmotic current between certain acid solutions—more particularly solution of hydrochloric acid—and water is subject to changes according to the different density and temperature of such solutions. Thus, for instance, in the case of hydrochloric acid of 1.02 density, the current proceeds from the water to the acid, whilst with hydrochloric acid of 1.015 density the current proceeds from the acid to the water; but if the temperature in this case be raised above 20° (68 Fahrenheit), the current will regain its original direction, viz., from the water to the acid. This fact is extremely curious.
